In conclusion, I wish to draw attention to the problem of maintenance. It is quite usual when a road is constructed to immediately forget about it, imagine it will last forever and look after new work. No matter how perfect is the construction of an earth road, whether top dressed with gravel or not, it requires constant care. The maintenance of earth roads is best accomplished by use of a split log drag or other implements of a similar device and if the drag is used with good judgment the cost is very little in comparison with the cost of repairing or reconstructing the road if allowed to go to pieces. Earth road repairs or reconstruction become unnecessary in proportion to the increased care in maintenance.

WATER POWER POSSIBILITIES IN ALASKA.

W. P. Lass, in an address on March 16, in New York City, before the American Electrochemical Society, declared that a proper development of the water power in south-eastern Alaska would be more valuable than either the gold mines or fisheries. He contended that the greater part of south-eastern Alaska, although undeveloped, unsurveyed and unprotected has been held in national forest reserves and little attention has been paid by anyone to its development and utilization. The present generation should use efficiently the great water supply of Alaska for power. It is an ever-flowing source of power that lost to-day can never be regained.

INTERNATIONAL CONFERENCE ON CITY PLANNING.

On May 25-27, there will be held in Toronto the International Conference on City Planning. Models, maps, plans and diagrams will be exhibited, illustrating the latest practice in Europe and America. Canadian cities and towns, and Canadian architects and engineers are cordially invited to send exhibits. All communications should be addressed to W. S. Lecky, Commission of Conservation, Ottawa, Ont. The exhibits may be classified under the following heads: Planning of Streets; Water Supply and Sanitation; Parks and Playgrounds; Waterways, Docks and Bridges; Railroads and Transit; Helping Industrial Prosperity; Garden Cities and Suburbs; Housing the People; Civic Centres and Public Buildings; Comprehensive Plans. Canadian social reformers will derive much benefit by attending this conference, listening to the addresses, taking part in the discussions, and by an inspection of the instructive exhibits that will be there shown.

SEWAGE COLLECTION AND TREATMENT IN PHILADELPHIA.*

By George S. Webster, Chief Engineer.

THE sewers of the city of Philadelphia as originally built discharged the crude sewage directly into the rivers and nearby streams, this not being considered objectionable at that time; but as the population increased and many tributary sewers were constructed, the smaller streams became seriously polluted and the Delaware and Schuylkill rivers, from which the city's water supply is taken, became so contaminated that in order to protect the public health it was necessary to take measures to alleviate the conditions.

The first work undertaken, commenced about the year 1883, was the construction of an intercepting sewer along the east bank of the Schuylkill River, from tidewater below Fairmount Dam to approximately the northern boundary of the city, with a main branch extending north along the Wissahickon Creek, thus keeping out of the water supply taken from the Schuylkill River all the sewage, collected in an extensive system of separate sewers, from Manayunk, Roxborough, Falls of Schuylkill and the portions of Germantown and Chestnut Hill lying in the Wissahickon and Schuylkill watersheds within the city limits. Recently an intercepting sewer has been constructed along the east bank of Cobbs Creek, to collect the dry-weather flow and first flush of the rain discharged from the combined sewers into that stream, which had become so seriously polluted as to be objectionable to sight and smell; and within the past two years an intercepting sewer has been built along the Pennypack Creek, in the north-eastern part of the city, to collect the sewage from the village of Holmesburg and from three large municipal institutions and convey it to treatment works, where it is purified sufficiently to protect the water supply taken from the Delaware River.

The city of Philadelphia has, therefore, what may be considered three systems of sewers: The combined system, which covers by far the larger part of the city; the separate system, which has been adopted in the areas adjacent to the portion of the Schuylkill River from which the water supply is taken, and the intercepting sewers along Cobbs Creek and Pennypack Creek.

The city is now engaged in the preparation of a comprehensive plan for the collection and treatment of its sewage, for submission to the state department of health, and the work which is now being constructed is in harmony with the plans which will be recommended. The investigations which have been carried on include a large number of studies of possible methods of collecting the sewage, the operation of a sewage experiment station, sanitary surveys of the water-courses and rivers, and the construction and operation of a plant to treat the sewage in one section of the city adjacent to the water supply. The magnitude of the problem will be appreciated when it is considered that the area of the city is 130 square miles, that it has a population of 1,650,000, and that the water consumption is approximately 200 gal. per capita daily; this, with the infiltrated ground-water from the older sewers, produces at the present time a large volume of sewage, estimated at 400,000,000 gal. a day.

The problem of sewage disposal in Philadelphia is twofold: first, to collect the sewage from the present system and abolish the nuisance which now exists in the large creeks and lower Schuylkill owing to the insufficiency of diluting water, and to carry it to distant points for treatment; and second, the protection of the public health by the treatment of the sewage, which is now and in the future will be discharged into the Delaware River, this treatment to be carried to such a degree that the drinking water can be safely and economically purified before delivery to the consumer.

It is of great importance, in preparing designs both for the collecting system and the treatment works, that relief may be given from the present objectionable conditions in the shortest possible time, that the work may be carried on economically and advantageously from time to time as funds become available, that each step taken may give some relief, and that it will not be necessary for the completion of the entire project before benefits may be obtained.

It was found early in the investigations that the cost of installing the separate system in those parts of the city already sewered on the combined plan would be prohibitive, for in addition to the cost to the city of laying sewage pipes in every street, the plumbing fixtures in all buildings connected to the sewer system would have to be rearranged so that the sewage and the rainwater could be carried in separate conduits. This latter expense, which would amount to many millions of dollars, would have to be borne by the individual owners.

In the design of sewers for the purpose of carrying sewage only, the factors used are the contributing population, water consumption and the amount of infiltrated ground water. It is quite common practice in many cities in designing sewage sewers to calculate that they shall run half full, when carrying a water consumption of 150 gal. per capita from the population tributary. To reach a conclusion as to the quantity of sewage to be treated by the city or Philadelphia in the future, and to obtain data for the design of the intercepting sewers, gaugings were made of the dry-weather flow of a number of main sewers, some of which were located in solidly built-up areas and others in partly built-up districts, and from the factors thus obtained estimates were prepared, based upon the probable increase and density of population, of the quantity of sewage that must be cared for in the future, the estimates and population curves being projected to the year 1950.

The amount of sewage flow determined by the gaugings in all cases included the infiltrated ground-water, no practical way appearing by which it could be differentiated from the sewage proper. As a majority of the sewers in which gaugings were taken are of considerable size and length, the variation between the maximum, minimum and average rates of flow is not as great as in smaller sewers. The mean of all the gaugings showed that the maximum flow was 128 per cent. of the average, and the minimum 78 per cent. of the average.

In addition to the flow of sewage, it has been decided to admit into the intercepting sewers, through automatic regulators, the first flush of the rain, which is usually as polluting as sewage, and the amount to be admitted has been fixed at 10 per cent. of the maximum dry-weather flow of the sewers, but a much larger percentage can be intercepted when the sewage is not flowing at a maximum rate. This additional 10 per cent. makes a storm maximum flow of 141 per cent. of the average flow.

When it is considered that the per capita consumption of water in Philadelphia is 200 gal. a day and that in the towns of England only about 40 gal. is used, it will be seen that by the arrangement proposed the degree of dilution of the sewage, in time of storm, compares

* Read before the Sanitary Section of the Boston Society of Civil Engineers, March 4, 1914.

well with the English practice of treating six times the normal dry-weather flow.

In studying the methods of disposal it has been found that the sewage may be treated with much less offense if it reaches the works in a comparatively fresh state before putrefaction has set in; therefore great care is being taken in the design of the sewer system that the velocity of flow shall not be less than that required to carry the materials in suspension. This is accomplished by providing proper gradients and by the exercise of care to secure smooth surfaces, avoiding all roughness and projections on the interior of the sewer where organic matter might find lodgment and be retained until putrefaction sets in and stench begins. Upon examination of many of the sewers in Europe there was no odor noticeable because the interior surfaces were smooth, either vitrified tile or smooth, glazed brick being used, and all connections so made as to provide a natural flow without the creation of eddies where deposits might occur. It is, therefore, recognized that a solution of a part of the problem of sewage treatment is to construct sewers with smooth interiors and to keep them clean and inoffensive.

In designing the collecting system, it is proposed to construct intercepting sewers at two levels, and in this way to utilize the potential energy in every foot of head and carry to the treatment works by the high-level interceptors the greatest possible volume of sewage, and thus reduce to a minimum the quantity to be pumped.

The collecting systems in many European cities are constructed so as to convey the sewage to one or more suitable locations for treatment, and care is exercised in their designs to secure the greatest economies.

Sanitary Surveys.—There are in Philadelphia five large creeks and the Schuylkill River, all of which are tributary to the Delaware River, which forms the eastern boundary of the city. Poquessing Creek flows through a territory but little developed, and is, therefore, not at the present time polluted. The sewage formerly discharged into Pennypack Creek and Wissahickon Creek has been intercepted and the water in these streams restored to a normal condition. A large part of the sewage on the Philadelphia side of Cobbs Creek has been intercepted and the condition of the water in this creek greatly improved. Frankford Creek, which empties into the Delaware River about five miles south of the Torresdale Water Filters, flows in part through a densely built up and industrial part of the city and receives crude sewage from about 140,000 people. It has several dams along its length, and, therefore, low velocities. The water is not only grossly polluted by the discharge of sewage into it, but the deposits of sewage origin upon the bed of the creek add to the nuisance.

The Schuylkill River flows through the city in a generally southerly direction, and about midway there is a dam which forms the end of tidal influence. The section of the river north of the dam has been protected within the city limits by intercepting sewers. Into the tidal portion of the river below the dam, however, there is now being discharged the sewage from about 455,000 people. At times of drought almost the entire up-stream flow is used for water supply, leaving a very inadequate volume of diluting water for the sewage from this large population. The examinations made during the summer months showed the water in this part of the river to be depleted of dissolved oxygen. Furthermore, the tidal velocities in the lower part of the Schuylkill River are insufficient to maintain the sewage matter in suspension, so that in addition to the polluted condition of the water, the putrefying deposits upon the bed of the river increase the nuisance, particularly in warm weather; but as in the case of Frankford Creek, above described, the natural sedimentation processes and the gasification of the resulting sludge, together with the refreshing action of the tide, lighten the load of organic matter placed upon the waters of the Delaware River.

The Delaware is one of the large rivers of the United States, and forms the natural drainage for portions of the states of Pennsylvania, New York and New Jersey. The normal flow of upland water is at the rate of 4.050 sec.-ft., in addition to which there is a tidal range of 5½ ft., and it is estimated that during the ebbing of the tide 2,421,000,000 cu. ft. of water flow past the city. As the sewage of the city at present and the effluent from the treatment works in the future must be disposed of in the waters of this river, its present condition has been examined with considerable care and it was found that with the exception of the docks, where sewers discharged, the Delaware River is successfully disposing of the crude sewage of the present population of Philadelphia in addition to that of the neighboring towns. Even in summer weather and in times of extreme drought, there has been no nuisance or offense created, although the amount of dissolved oxygen in the river has been small. The surveys indicated that the river water after passing beyond the points of discharge of the sewage of the city gained rapidly in its oxygen content. The high velocities, due to tidal flow in the river, maintain the sewage matters in suspension, and the examination shows that the entire bed of the river (excepting the docks) is clean and free from deposits of sewage origin.

It must, however, be realized that, with the increase in the population and the consequent added load placed upon the river, its oxidizing power will soon be overtaxed and that the time to begin the building of the collecting and treatment works is at hand.

Treatment Works.—The sanitary surveys of the water-courses in Philadelphia show that sewage must be excluded from tht creeks and the Schuylkill River, and that the treatment works must be located so as to discharge their effluents into the Delaware River in order to utilize to the fullest extent the great diluting and oxidizing capacity of that river.

It is proposed to locate the first treatment works in the north-east section of the city. The collecting system tributary thereto will eliminate the pollution of Frankford Creek and also prevent the discharge of crude sewage into the Delaware River within the tidal influence of the Torresdale Water Filters, which provide three-fifths of the city's water supply. The degree of treatment required at this works must, therefore, be based upon a hygienic standard in order that the public health will not be jeopardized by overtaxing the economical and safe operation of the water filters.

The second treatment works will be located in the south-west part of the city, near the mouth of the Schuylkill River, the most distant point within the city limits from the source of water supply. The collecting system tributary to this works will eliminate the pollution of the lower Schuylkill River and will result in concentrating the sewage from over half the population of the city at one point for treatment. As the effluent of this works will be entirely below the influence of the city's water supply, the degree of treatment required need only be sufficient to prevent nuisance in the Delaware River.

It appears to be economical to construct temporarily a clarification works in the south-east district, to care for the sewage now discharged into the Delaware River below the centre of the city.

Treatment.—In selecting methods for the disposal of the great volume of sewage produced in large cities, the adaptability of the various processes to a comprehensive plan must be considered so that the treatment works may be constructed by successive steps as needs arise for more refined treatment and as funds become available. It is desirable to obtain intensive methods, so as to secure a maximum of efficiency upon a minimum area of land, but in all cases exercising care to prevent nuisance from odors.

Various methods for the treatment of the sewage of the city of Philadelphia were studied, and those best adapted to the local conditions selected.

It has been frequently urged that the sewage of the city could be purified to advantage by applying it to farm land. Mr. John D. Watson, after years of experience, aptly states that this method of disposing of sewage "may be ideal in theory, but it is difficult, if not impossible, to obtain the ideal on a farm of large size." Berlin and Paris dispose of their sewage in this way, but, owing to the small volume of sewage which can be treated per acre, large areas of suitable land are required.

The Metropolitan Sewerage Commission of New York City has estimated that 175 square miles of land would be required to treat the sewage of that city if it were applied at the rate of 12,000 gal. per acre, and that the cost of this method of treatment would be $153,-000,000, and, therefore, dismissed it as being impracticable. The city of Birmingham, England, has abandoned its sewage farms and substituted the more intensive biological method, and the same course will probably be followed in Paris.

To treat at the present time the sewage of Philadelphia on farm land would require an area of approximately 60 square miles. To secure this amount of land in Pennsylvania adjacent to the city would be prohibitive on account of the cost, and would be opposed by citizens and property owners, hence this method of treatment need not be further considered.

London, the largest city in the world, with a population of 6,000,000 people, situated on the banks of a river with but little larger flow of upland water than the Schuylkill, disposes of its sewage by removing about 75 per cent. of the suspended matter by chemical precipitation and depends upon the oxidizing power of the river to accomplish its ultimate purification. That this is being successfully accomplished may be seen from the diagram which was prepared by Sir Maurice Fitzmaurice, late chief engineer of the London County Council, showing the percentage of saturation of the Thames River with dissolved oxygen, in connection with which he states: "With respect to the minimum amount of dissolved oxygen that should be present to prevent offense, it is rather difficult to answer this correctly, but I may say that the only complaint in recent years was for a short time in 1901."

While this method has been successfully used in London, it would not be applicable to Philadelphia, on account of the long haul to dispose of the sludge in the ocean, over one hundred miles distant. Another objection is the large quantity of sludge produced. From the best information available, it appears that the sludge, containing about 95 per cent. water, resulting from this method of treatment, amounts to 800 tons per day for a population of 500,000 people.

The city of Manchester, England, has probably the largest installation of contact beds. These are found to be expensive to operate and fail to produce an effluent up to the requirements of the Rivers Board. The concensus of opinion among experts in England seems to be that contact beds for a large installation are not as efficient as percolating filters.

From the results obtained at the Philadelphia Experiment Station and from the plant in operation at the Pennypack Creek, confirmed by the testimony of the city engineers who inspected a number of plants in Germany, it has been found that the two-story sedimentation tank, known as the Emscher tank, offers the best solution for the preliminary treatment of the sewage. The advantages are that the separation of the settling sewage from the digesting sludge maintains the sewage in as fresh a condition as it enters the tank, that it is equal in efficiency to any other type of tank in removing the suspended matter with shorter retention periods, and that the sludge withdrawn is without offensive odor, is smaller in volume than sludges resulting from other processes and more easily dried, and is so thoroughly decomposed that it resembles garden soil, and may be used for filling in low lands without nuisance.

It is the purpose to recommend for the north-east and south-west treatment works the following processes in sequence: Coarse screens to restrain the large floating objects, grit chambers designed to intercept the inorganic matter only, two-story sedimentation tanks of the Emscher type, and percolating filters or such other improved methods of oxidation as may be developed by the time this refinement is needed. All of these processes are so related that they can be incorporated in the work successively; each one is the most intensive of its kind, therefore a minimum amount of land will be required for the works.

At the South-east Works it is proposed temporarily to clarify the sewage either by fine screening or by the tankage method and then to discharge it without further treatment into the river. If a more refined treatment is required in the future the effluent from this plant may be carried to the South-west Works, where ample area is being provided for additional processes.

The full utilization of the diluting and oxidizing power of the river water largely depends upon securing a thorough mixture of the effluent from the works and the water of the river. At each of the three proposed treatment works for Philadelphia it is planned to accomplish this by discharging the effluent through submerged outlets into the main channel of the river.

The distribution of sewage over the surface of percolating filters is one of great importance, as efficient distribution will allow the use of high rates. At Bolton and at Hampton, in England, a travelling distributor is used. This requires but little head, but it is doubtful if it could be successfully used in countries subject to severe winter weather. At Wilmersdorf, Germany, and in a number of English plants, there are percolator filter installations in which distribution is effected by means of rotary arms. This method accomplishes good distribution, but has not been looked upon with favor in America. At Birmingham, distribution is through fixed nozzles operating under a constant head, and this method was followed in the early American installations, but it results in uneven application of the sewage. Latterly this has been improved by the use of the tapered dosing tank with syphonic discharge.

At the Pennypack Creek Works in Philadelphia there is in service a method of distribution through fixed nozzles, operating under a fluctuating head, which yields results equal to that from a mechanical distributor.

The Pennypack Creek Sewage Treatment Works.—As a part of the work of disposing of the sewage of the city and of protecting the water supply, a treatment

works has been constructed and is now in operation on the banks of the Pennypack Creek, which empties into the Delaware River 2,000 ft. from the Torresdale water filters. Into this creek there was formerly discharged the sewage of the village of Holmesburg and the large municipal institutions located nearby. Intercepting sewers have been built along the creek, and they conduct the sewage to a pumping station, where it is coarse-screened and passed through a grit chamber and then forced to the treatment works, one-third of a mile distant. The plant is designed ultimately to treat 2,000,000 gal. per day and at the present time it is receiving approximately 1,000,000 gal. daily.

The sewage first enters two Emscher tanks, which are of the radial flow type, 30 ft. in diameter and 32½ ft. deep, and having a normal retention period of 2½ hrs. The sludge is withdrawn from the bottom of these tanks through a pipe line, and is discharged by gravity upon a sludge-drying bed composed of layers of sand placed upon broken stone and under-drained by agricultural tile. Instead of the usual method of collecting the effluent of the Emscher tank into a dosing tank from which it would be discharged by a siphon upon the percolating filter, an equalizing tank has been constructed into which the effluent flows. The bottom of this tank is connected by a 24-in. cast-iron pipe with the distributing system of the percolating filter, and in this line between the equalizing tank and the percolating filter is placed a butterfly valve. The opening and closing of the butterfly valve is controlled by a cam, which is operated through gearing by a water-wheel driven by a small flow of Emscher tank effluent.

The shape of this cam was designed experimentally so as to make the spray from the fixed nozzles alternately move back and forth from the nozzle to a line which produces about six inches overlap of the sprays, and by this means a distribution has been obtained practically equal to that from a mechanical distributor.

To meet the variation in flow, due to the daily fluctation and to storms, the equalizing tank is electrically connected to the operating machine so that when the flow decreases and the level of the sewage in the tank falls to a predetermined elevation, the machine shuts down and the percolating filter is thrown out of service. When the flow increases and the water rises in the tank, a different cam from that generally in service is automatically thrown in, which causes a longer period of display of the nozzles and cares for the increased flow.

The percolating filter is one acre in area, and is divided into five bays, each having its own main distributor. Taylor square nozzles are used, spaced 10.8 ft. apart. The medium is 6 ft. of crushed trap rock, from 1 in. to 3 in. in size. Semi-circular vitrified clay underdrains are laid on a concrete floor, which slopes to the main effluent collectors.

As the function of this plant is the protection of the water of the Delaware River in the immediate vicinity of the intake of the Torresdale water filters, the state department of health required the disinfection of the effluent of the percolating filters, and a plant for this purpose was installed on the line connecting the percolating filters with the final settling basin, consisting of a mixing tank, which rests on the floor of the house and from which the bleach cream is forced by a centrifugal pump to either one of the two solution tanks. Before the bleach solution is added to the sewage it is diluted by a stream of water, and the very dilute solution flows through a lead pipe, perforated with a large number of small holes, and which lies horizontally in the channel carrying the effluent from the percolating filters. In this way a complete admixture of the disinfectant with the sewage is accomplished, and with only about 25 lbs. of dry bleach per day, which represents one part per million available chlorine, an almost sterile effluent has been produced. The records show that over a period of nineteen weeks only upon one occasion were B. coli found in the final effluent. After the sewage has been disinfected it is retained for about two hours in a shallow final settling basin and is then discharged into the creek.

The sewage as received at the treatment works is both fresh and dilute, and by keeping clean the surfaces with which it comes in contact, and by passing it through each of the processes as rapidly as possible, the plant is operated without any odor.

The grounds around the works have been made attractive by the maintenance of well-trimmed grass areas and by planting shrubs and flowering plants.

The sludge withdrawn has been low in moisture, generally about 75 per cent., has contained a considerable amount of gas, and each time it was withdrawn it has been found to be blacker and more granular, showing that the ripening period has been passed and that typical sludge has been obtained.

The final effluent as discharged into the creek has invariably been free from an appreciable amount of suspended matter, perfectly stable and nearly sterilized.

The work so far accomplished has demonstrated the feasibility of the methods suggested for the comprehensive treatment of the sewage of the city. The state board of health having been in touch with the work so far completed, it is anticipated that the plans to be recommended will meet with its approval; and it is hoped that funds will soon be available to commence the work on the larger installations.

AUCTION OF PULP LIMITS IN ABITIBI AND LAKE ST. JOHN.

Announcement has been made that the Quebec Government has decided to open new districts to lumber and pulp industries and will auction off limits in the Abitibi and Lake St. John districts during the months of August and October. In the Lake St. John region the territory to be opened is north of the lake and in basin of the Mistassini and Rat Rivers. In the Abitibi it is situated south of the Transcontinental, but on the north slope in the basin which empties in James Bay. This tract is traversed by the Poisson Blanc, Harricana and Belle Rivers. Both limits have been most carefully surveyed by the Forestry Service.

These concessions will call for the development of the water powers in the districts and will carry the obligation to construct pulp mills of a specified capacity within three years. The delay between now and August is to allow opportunity for exploration and permit of advertising the proposed auction, not only in Canada, but also in the United States, Great Britain and France, as the Government wishes to attract the attention of foreign capitalists to the great natural resources of the province.

The Government has appointed five official guides to further the interests of colonization in the Abitibi district and show settlers what that district has to offer.

A $2,000,000 corporation to provide electric power and lighting facilities for the Santa Ynez valley, the northern end of the county and all of San Luis Obispo county, has filed articles of incorporation at Santa Barbara, Cal., being the Midlands Counties Public Service Corporation. The present place of business is in Los Angeles. The company has acquired the power plants at Santa Maria, San Luis Obispo, Lompoc and other points, and plans for immediate extensions are being made. The new company is a subsidiary of the San Joaquin Light and Power Co. and power will doubtless be supplied by the immense plants of the San Joaquin company in the Sierra Mountains.

CONTENTS OF THIS ISSUE.

CAMPAIGN AGAINST SMOKE IN ENGLAND.

There is a steady progress to the movement in Great Britain for smoke abatement and economy of fuel. During the past year much attention has been devoted to the publication of literature on improved methods for industrial and domestic consumption of coal, while the former side of the question, atmospheric pollution, is being followed up energetically. This spring some 15 of the largest cities have taken up the work of accurate measurement of smoke discharge, and it is expected that comparative records will have been obtained before the year ends.

One notable fact which the movement has brought to light in London is the rapid growth of the employment of electricity and gas for domestic purposes and the corresponding decrease in the use of coal.

It is stated that a bill will shortly be submitted to parliament whereby the existing laws may be consolidated, and another to extend disciplinary powers to local authorities against the emission of black smoke by industrial plants.

Four years ago educational classes for enginemen and firemen were inaugurated, under the direction of smoke inspectors of several cities. These have been very successful. The training of firemen is resulting in much encouragement to those who are attacking the smoke problem.

ECONOMY IN ROAD BUILDING.

The best form of road building economy is that which has for its basis the careful selection of a type of road or pavement that will best suit, during its entire lifetime, the conditions with which it has to contend. Analogous to this is the necessity, before any such selection can be made, for an exhaustive study of what those conditions have been, are, and are likely to be as long as the proposed pavement is in service. Then the exercising of judicious care and watchfulness over it, when laid, will prolong its usefulness; and, taken altogether, the result will be an economical piece of road building.

Occasionally one encounters, however, methods of figuring road costs that are instructive and that may be applied with comparative ease to an accumulation of data on costs of building, maintenance and repairs. An analysis of this nature might be expected to bring out interesting features which do not appear on the surface of the available road statistics.

An article appeared in last week's issue, which analyzed from a standpoint of 20-year economy the heavy traffic roads of some of the eastern States. It presented an interesting method of figuring road charges of one kind and another, e.g., capital, maintenance, renewal and interest charges. The results which were derived, however, bear a very marked dissemblance to those which Canadian practice has established, affording an excellent opportunity for a portrayal of that with which our municipalities are most concerned at the present time—the serviceability of Canadian roads and pavements.

It would be interesting for our readers to review the findings which *The Canadian Engineer* published in its issue of September 25th, 1913, as a result of an investigation into the whole subject of improved roads and streets in Canada. The returns from all the principal cities and towns, as summarized there, display a wide variation from the results which Mr. Trautschold derives in his treatment of certain conditions to be met with in New England. Where he has figured brick and stone to outclass

asphalt and wood block in the matter of relative 20-year economy when built under those conditions, with capital bearing interest at various rates per annum, road statistics in Canada, as indicated by the actual results obtained, are the complete reverse of his conclusions. This is so universally the case throughout the provinces that we find, as a result, for every mile of brick and stone pavements combined, there are two miles of wood block (chiefly treated, in which state it was introduced into Canada only ten years ago) and eight miles of asphalt pavement. In our cities there are upwards of 800 miles of paved streets, only about 50 miles of which are built of brick and stone. When one considers the special conditions in which these types present favorable characteristics, viz., where graded streets are to bear heavy traffic, where noise does not count, or where unsanitariness is not a factor (if such is anywhere the case nowadays) the proportion, 800:50, may not be far astray.

As stated, the economy of road and pavement work is chiefly a matter of choosing the best pavement to suit the conditions to be imposed upon it. Care in ascertaining the requirements, and in selection, with those requirements prominently in the foreground, are the essentials. Without them, no comparable results need be expected from the application of any formula.

Although the results would scarcely be recognizable when compared with Mr. Trautschold's, owing to entirely different conditions and quantities to be reckoned with, Canadian road engineers may apply to advantage the method of procedure laid down in the article referred to. From their own personal experiences, they will, of course, see the necessity of using figures that comply more strictly with their practice, (such, for instance, as the cost of maintenance) than those used in exemplifying the formula.

LETTER TO THE EDITOR.

Re "Some Large Concrete Bridges."

Sir,—In the article entitled "Some Large Concrete Bridges," beginning on page 698 of May 7th, 1914, issue of *The Canadian Engineer*, there are several slight errors and omissions to which I beg to draw your attention, in order that readers will in no way find the interesting article misleading.

For instance, in the opening paragraph of the article it is stated that "there has been a gradual increase in the length of the spans and length over all," etc. This statement is incorrect, as the longest concrete bridge was one of the first ever built. It was built in France prior to 1865.

In describing the Wissahickon bridge, the writer states that "prior to this all traffic had to make a wide detour," etc. He apparently overlooks the fact that there had previously been an old wooden bridge on the same site. Some of the largest recent bridges are not mentioned, such as that at Auckland, and the statement is made that the Riverside bridge was built contemporary with that at Walnut Lane, whereas it was actually completed two years before the Walnut Lane bridge was begun.

Further, it is stated that a recent bridge spans the Connecticut River in the city of Washington.

H. G. TYRRELL,
Bridge and Structural Engineer.

Evanston, Ill., May 12, 1914.

FIBRED ASPHALT PLANT FOR CANADA.

Geo. A. Henderson, of St. Albans, West Virginia, announces that a Canadian company has been organized to manufacture the new pavement "Fibred Asphalt," patented in Canada by Mr. Henderson last December. A $20,000 factory will be erected in Toronto in June, where graded hard-wood fibre will be impregnated. A test pavement, the first of fibred asphalt in Canada, will be laid in Toronto within a few weeks, the first ever laid being at Memphis, Tenn., in 1912. The Good Roads Year Book of the American Highway Association publishes the following:

"The invention relates principally to the art of denaturing hard-wood and preserving it in the following manner: A billet of hard-wood is shredded into small particles of ununiform lengths of 1½ inches down to wood flour, the flour itself being eliminated from the aggregate by screening. The particles are denatured by the process used by the tannin extract manufacturers, in which process all sap, essence and the more evaporable and deteriable elements in the wood are extracted, the remaining particles being thereby rendered abnormally enlarged and porous. In their subsequently dried and heated condition the wood particles, because of their porosity, are susceptible of impregnation, by absorption, by a non-deteriable, non-evaporating matter (such as asphalt), in lieu of the sap, etc., removed. The heating of the dried particles to prevent the premature congealing of the molten asphalt before reaching the particles' pores, has also for its object the partial contracting of the enlarged particles. The consequent contraction in the size of the particles' pores correspondingly reduces the amount of asphalt required to completely fill them.

"The wood fibre is a waste product of tannin extract manufacturers, who use hard-wood and no bark in their process. The particles are taken from the leaches on endless belts; dried, screened, heated and then mechanically mixed with a predetermined uniform percentage of asphalt, sufficient to fill the pores and voids in the mass when finally contracted and compressed. The material, in its partially impregnated and partially contracted condition is deposited at the mouth of its mixer into moulds 4 by 6 feet, these blocks being compressed on all sides only 3 to 4 inches, and allowed to cool, when they will remain intact for shipment, but are readily disintegrated in a breaker stationed at the front of a portable re-heating machine, designed to travel over the road to be paved, in which machine the coated particles are deposited and heated to from 250 to 275° F.

"This heating results in the final contraction of the fiber to its normal size, as it was before being chipped from its original log, and the entrapping of its asphalt content, thereby insuring penetration to the most minute pore of the fiber, thus thoroughly preserving it, without affecting its natural resiliency. The mass emerges from the rear of the re-heating machine in a continuous 18-inch flow onto the previously prepared road base, where it is mechanically spread 4 inches thick, steam roller compression immediately reducing it to a compact mass 2 inches thick. The interlocking of the ununiform preserved sinues of the hard-wood, in conjunction with the substantial penetration of the binding asphalt, in addition to surrounding the particles, is relied upon for durability.

"Fibred asphalt may be laid on any substantial foundation, such as old macadam, crushed stone, concrete, old brick, granite or wood blocks or cobble stones. For use on country roads a curb or shoulder is not necessary."

SOME FACTS ON REINFORCED CONCRETE.

By H. O. Hoffmann, Civil Engineer, Montreal,
Graduate of Polytechnic University of Zürich, Switzerland.

EXPERIMENTS which the writer has made lately in regard to construction in reinforced concrete and static analysis in general have prompted an elucidation of this matter from various points of view. First of all, one is confronted with the fact that men who appear to hold some distinction in their profession are often decidedly in need of clearness as to the correct distribution of the forces in the individual members of a structure. In order to guard against any eventual accidents, many designers are led to exaggerate the proper dimensions, with the result that not only less economical forms are obtained, but generally, also, there is no certainty of producing a secure structure.

This is one thing that tends to create prejudice against reinforced concrete as a reliable building material. Moreover, this method of tackling such problems is directly at variance with the whole science of the calculation of reinforced concrete structures, and hinders a due development which building in reinforced concrete has merited in other countries.

Careful studies in the designing of modern reinforced concrete structures have caused them to be classed as economical, since the specific qualities of the composing materials, concrete and steel, each in its place, are fully utilized. If these economical principles are neglected, reinforced concrete can never seriously compete against other building materials. To do justice to the proper designing of reinforced concrete, the designer must not rely only on a certain set of standard rules, as generally each construction requires an individual treatment in order to gain the most economical results, which in turn leads, in nearly all cases, to very simple structures. These, being very often statically indeterminate, may be computed only by a trained calculator.

A designer who is not versed in the statical analysis invariably commits the very fault described above, thereby increasing the cost of erection without rendering the structure safe. One need only repeat the warning given by Mr. V. J. Elmont, A.M.Can.Soc.C.E., in August 28th, 1913, issue of *The Canadian Engineer*, page 361, which reads as follows:

"This proves once more that the approximate figuring usually employed by designers without knowledge of calculating statically indeterminate structures, is nothing less than a menace to safe construction."

Furthermore, there is a stubborn disinclination against the employment of the plain round steel bars, and though these are much cheaper and more easily handled, all kinds of expensive patented bars of twisted, corrugated, etc., forms are mostly preferred. It is not the purpose here, however, to discuss the necessity of the employment of patented bars, or to show that this is based on an absolutely faulty assumption, for it would only be a recapitulation of the very statements given in the book written by Professor Moersch, formerly Professor in the Swiss Polytechnical University, whose treatise on reinforced concrete is widely known and favored by American civil engineers.

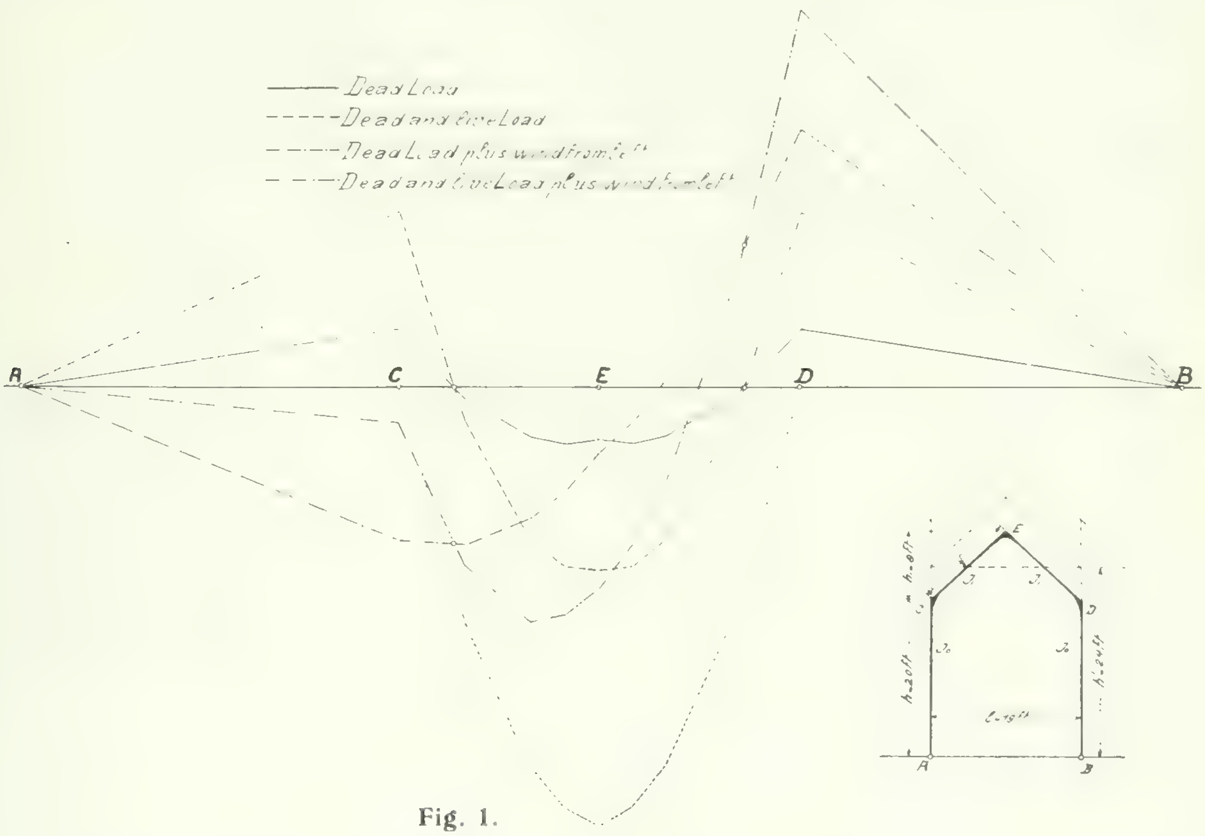

Fig. 1.

The following example, taken from practical experience, will tend to prove that only a correct statical calculation may enable us to utilize the advantages of reinforced concrete and successfully compete against a structure of steel. Moreover, if specific qualities are demanded, such as fireproofness, the most favorable room capacity, speedy erection, unlimited durability, omission of expenses for maintenance, etc., structures in reinforced concrete may claim the distinction of combining these

qualities in a greater degree than any built of other materials.

The writer does not consider the theory correct that the high cost and difficulty of securing skilled labor in this country forbid a more extensive application of this method of building. To contradict this, it may be stated that in the Balkans, he has succeeded in carrying out such work very economically, despite high cost of labor and extra expenses for specially skilled men. On other occasions he has, with wholly unskilled labor, accomplished very difficult work, employing the local natives, such as Wallachs, Albanese, etc. It may be added that the world famous firm, Hennebique, has used Egyptian Arabs, with whom they have effected good results on rather difficult pieces of work. It is simply a case of putting the right man in charge of construction, one who is of absolutely reliable character, and who thoroughly understands the whole system of building in reinforced concrete.

In Fig. 1, showing the bending moments, the elements of the moment are plotted on the laid-off axis of the frame. For the sake of simplicity, we substitute for the correct curve a polygon. The elements consist of: Dead load; dead load plus live load; wind from left plus dead load; wind from left plus dead and live load. The resultant of the maximum moments which is determinative for the dimensions of the structure will be found in the diagram for maximum bending moments.

In this case may be neglected also the longitudinal and transversal forces.

This method, however, was not comprehended by the gentleman for whom the writer designed the construction. Instead, he proposed the summary proceeding to distribute the weight on the transom, thereby presuming this

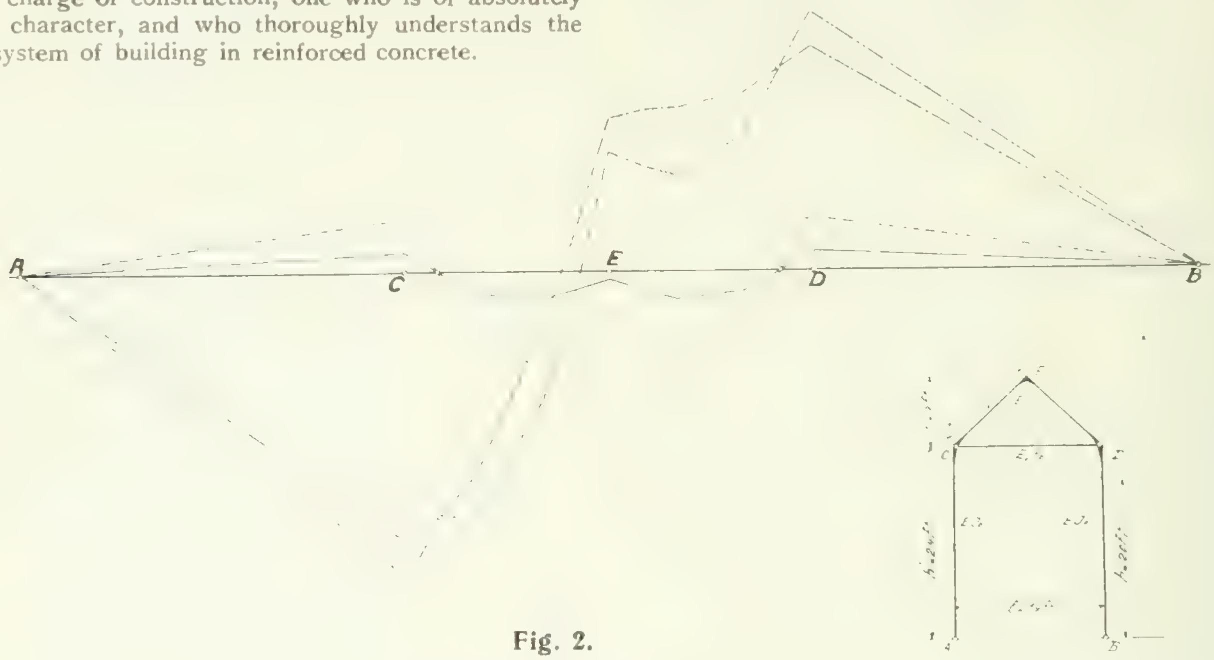

Fig. 2.

part of the structure to act as a plain beam, transmitting the weight to the two columns, which would have to be stiffened by the employment of a tension plate, and may be calculated as ordinary columns.

Such an assumption is absolutely arbitrary, consequently not in accord with the real circumstances. Proceeding in this manner, the structure does not only lose its monolithic character but the result is a mere farce of correct designing.

Realizing that the bending moment of the beam (dotted line in Fig. 1, for dead plus live load) amounts to more than twice the value of the moment in the vertex of the transom, it consequently requires more material for its erection.

Moreover, we cannot neglect the frame effect of the structure simply by assuming conditions which do not exist. Yet there appear important wedging moments, especially under the influence of a strong wind, whose effect must be considered. The posts calculated and constructed as plain columns could not stand these stresses. Thus the amount of material for erection of the frame is greater, yet the stability is more than doubtful.

If, to accommodate the "sense of statics" of such employers one takes refuge in putting in a tie, the height of the structure, in order to keep within the clearance limits, will be increased by 4 feet. With this method the frame becomes a double statically indeterminate structure, which has to be calculated as follows:

As a further obvious example of the advantages of reinforced concrete as a building material, it is to be noted that in the United States and other countries it is fast replacing other materials.

In the following case is considered a tender for double-track coaling plants with sand-house in reinforced concrete. This is taken as a typical example of such construction, particularly the supporting structure for the sand-house.

A two-hinge frame is proposed, as shown in Fig. 1. Such a structure is single statically indeterminate. As statically indeterminate value we insert the horizontal thrust X, and calculate with the aid of the rules of Castigliano for the smallest deformation. In this problem the insignificant influence of the normal forces and change of temperature may be neglected. We have then

$$\int \frac{M}{EI} \frac{\delta M}{\delta X} ds = O.$$

and becomes

$$X = \frac{\frac{I_1}{I_0}\int_0^h M_0 y . dy + \int_0^s M_0 (h+y) dx + \frac{I}{I_0}\int_0^s M_0 y . dy}{(\frac{I}{I})2\int_0^h y^2 dy + h^2 \int_0^s ds.}$$

We denote the statically indeterminate values: Suppose that the horizontal thrust on the support to be denoted by X_1 and on the spring of the transom by X_2, using the well-known formulas:

$$(1)\qquad \int \frac{M}{EI}\frac{\delta M}{\delta X_1}ds + \int \frac{N}{EF}\frac{\delta N}{\delta X_1}ds = O.$$

$$(2)\qquad \int \frac{M}{EI}\frac{\delta M}{\delta X_2}ds + \int \frac{N}{EF}\frac{\delta N}{\delta X_2}ds = -\frac{X_2\, l}{E_0 F_0}.$$

the two methods, unless we consider that the frame with a tie is 4 feet higher and has the same cross-section as the frame without a cross-tie. For the construction of the latter frame it cannot be considered that saving of material is of the first importance, but rather that reduction of cost for labor for the frame without a cross-tie inasmuch as the correct workmanship for the tension plate (which, furthermore, would have to be suspended from the vertex of the transom) would increase the cost of the structure, and for the handling of the storage owing to the greater height. All these facts are of more importance

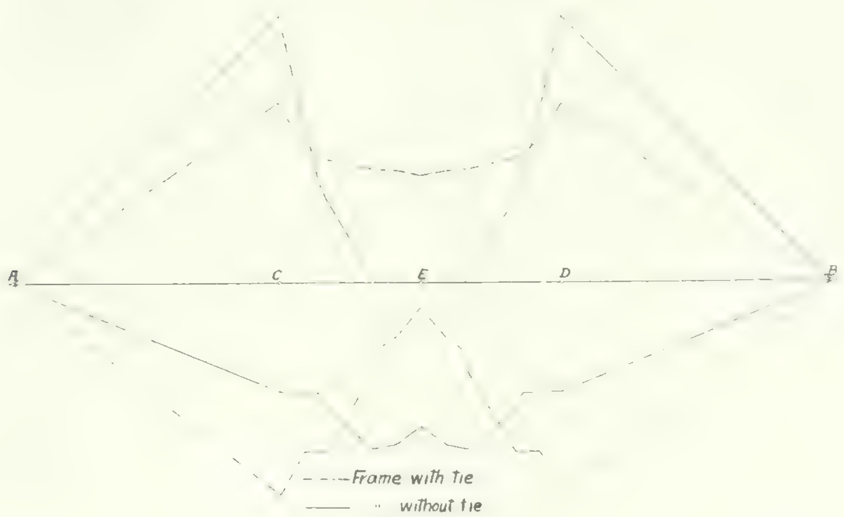

Fig. 3.

Notwithstanding the fact that the tie is embedded in concrete to protect it from the corroding effects of smoke, etc., and forms a part of the monolithic structure of the frame, the flexibility of the tie is not affected. This assumption has been found to be true on several similar constructions which the writer has designed and constructed.

Inserting in the equations the values of M, N, $\frac{\delta M}{\delta X_1}$, $\frac{\delta M}{\delta X_2}$, $\frac{\delta N}{\delta X_1}$ and $\frac{\delta N}{\delta X_2}$, for the individual members of the structure, we obtain:

$$(1)\qquad \int_0^h \frac{M_0 - X_1 y}{E I_0} y.dy + \int_0^h \frac{M_0 - X_1 y}{E I_0} y.dy +$$

$$\int_0^s \frac{M_0 - X_1(h+y) - X_2 y}{E F_1}(h+y)\,ds$$

$$-\int_0^s \frac{(X_1 - X_2)\cos\alpha}{E F_1}\cos\alpha\, ds = O$$

$$(2)\qquad \int_0^h \frac{M_0 - X_1(h+y) - X_2 y}{E I}\, yds$$

$$-\int_0^s \frac{(X_1 - X_2)\cos\alpha}{E F_1}\cos\alpha\, ds - \frac{X_2\, l}{E F_0} = O.$$

From these equations we may determine the two unknown values and find the moments shown in Fig. 2 again for all four methods of loading.

Comparing the curves for the maximum bending moments of both methods of calculation, there is at first no substantial advantage to be noticed adhering to either of

when we consider that such plants may be erected in quite a number of stations.

The above example is one of many tending to show conclusively that some structures in reinforced concrete may be designed on economical principles only with a thorough knowledge of statics.

COPPER AND SILVER MINING IN 1913 IN MICHIGAN.

Returns received by the survey in connection with mine production of copper and silver in Michigan in 1913 shows that the production of copper from ore mined in Michigan during 1913 was 135,853,400 lbs., having a value of $21,-[illegible], the copper being calculated at an average value of 15.5 cents a pound. The mine output was much smaller than the smelter production, as considerable material mined and milled previous to 1913 was smelted during the year. The production compares with an output of 218,1[illegible] lbs. in 1912, valued at $35,[illegible]. Due to the labor troubles which began July 23 and continued for the rest of the year, the output of all mines was greatly reduced in the latter half of the year, and several mines were not operated after July 23. The mines produced [illegible] tons of ore with an average copper recovery of 19.36 lbs. to the ton, compared with 11,411,941 tons of ore in 1912 with an average copper recovery of [illegible] lbs. to the ton. In addition to copper, the mines produced 205,17[illegible] ozs. of silver [illegible], compared with [illegible] 453 ozs. in 1912.

Writing upon the [illegible] of iron and steel in *Iron and Steel [illegible]*, [illegible] Mr. F. Rogers states that the crystalline structure frequently shown by wrought iron or steel which [illegible] repeated stress does not appear to be the result of fatigue, since in every [illegible] such failure [illegible] the author's notice, [illegible] fracture [illegible] [illegible] part of the metal. Examples of the failure of wrought iron are given in which such crystalline structures, in both the new and the fatigued metal, were due to the presence of [illegible].

STEEL PIPE MANUFACTURE.

THE following is a résumé of a lecture upon the manufacture of steel pipe, delivered by Dr. W. H. Walker, of the Massachusetts Institute of Technology, at a recent meeting of the American Chemical Society in Boston. The lecture reviewed the entire process of manufacture, from the sampling of ore at the mines to the testing of the pipe before shipment.

Iron is one of the most widely distributed elements in nature, but it is practically always found in combination with other substances, occurring largely in the oxide form. Chemically pure iron is extremely rare; its separation in the laboratory is a long and tedious process, and few engineers ever see it freed from combination with other elements. The production of pig iron in the United States has increased from 8,000,000 tons in 1896 to 31,000,000 tons per year at present. Forty-one per cent. of the total output comes from Pennsylvania, 23 per cent. from the Great Lakes District, 9 per cent. from Illinois, 4 per cent. from New York, and 6 per cent. from Alabama. The large coal deposits of Pennsylvania are important factors in the cheap local production of iron and steel. Some of the largest plants on this continent are the Gary, Ind., works of the Indiana Steel Co., the Lorain, Ohio, works of the National Tube Co., and the Chicago plant of the Illinois Steel Co.

The Lake Superior district is the largest producer of iron ore, and the Mesaba Range in Minnesota is the most famous present source of the raw material of the pipe industry. From the range to the steel mills of Pittsburg, the distance is about 1,000 miles. The ore beds are sometimes 600 ft. deep, with a heavy overhang. Steam shovels, efficient ore cars, excellent docking facilities and the loading of steamers by gravity are utilized to the fullest extent. An average steamer cargo of ore weighs 13,000 tons, and such a boat can be loaded in 31 minutes.

Unloading by cranes and multiple buckets consumes four hours. A modern blast furnace will produce 500 tons of iron in 24 hours, the furnace being 100 ft. high and 22 ft. in diameter at the bottom. To produce one ton of iron in a blast furnace there must be supplied eight tons of air, four tons of ore, two tons of coke and ½ ton of limestone. The furnace is tapped every four hours and the iron is tapped into sand molds or into ladles as conditions require. In a modern blast furnace 40,000 cu. ft. of air per minute is supplied at a temperature of 400 deg. C., and a pressure of 15 lb. per square inch. At Gary, all the gases of the furnaces are burned and enough power is produced by the gas engine and electric generating plant to operate the rolling mill, a cement plant and other establishments. Eight blast furnaces are installed at Gary.

From the blast furnace the iron is run into a metal mixer of 600 tons capacity, which reduces the casts from different furnaces to uniform temperature conditions, impurities being later removed in a Bessemer converter. When the iron has been purified by blowing air through the charge of metal in the converter, the charge is emptied into a travelling ladle and at the same time a certain amount of molten spiegeleisen is poured into the ladle with the iron to introduce into the metal a proper amount or carbon and manganese for the grade of steel required.

In usual practice a train of cast-iron ingot molds, with two ingots to the truck, is drawn by an engine beneath the pouring stand, and the hot metal is run into the molds through a nozzle in the base of the pouring ladle. As soon as the ingot is set, the mold is drawn from it by a hydraulic stripper, and it is lifted by an electric crane, and lowered into a soaking pit or heating furnace, where it is raised to the proper temperature for rolling. From the soaking pit the ingot is taken to the mill and passed through the blooming rolls, which reduce it in section reads for shearing into slabs and billets. Electromagnets are extensively used in handling billets. The billets in manufacturing pipe are re-heated and passed through a continuous mill consisting of a large number of rolls in pairs, placed one beyond the other at increasing intervals. As the billets or slabs are carried through each successive pair of rolls they are reduced in thickness and increased in length, until they issue from the last pair of rolls in the form of long, narrow plates called "skelp."

In the narrower strips, used for smaller pipes, the width is sufficiently uniform to eliminate trimming with shears, but the skelp for large pipes has to be carefully trimmed to the correct dimensions. In lap-welding, the plate is first laid upon a travelling table and has its edges bevelled. It is then heated in a bending furnace and rolled up into the form of a pipe with the bevelled edges overlapping. The material is heated and passed through concave welding rolls, between which a ball-shaped mandrel of a diameter equal to the interior of the pipe, is held in position by a long bar. As the skelp passes through the rolls the overlapping edges are squeezed together between the rolls and the mandrel into a perfect weld.

The rough pipe is then passed through sizing rolls and brought to the exact diameter required; then through the cross-straightening rolls, after which the pipe is rolled on a cooling table to prevent warping, and is finally forced by a hydraulic press through the dies of a straightening machine. The ends are then trimmed and threaded, and after being screwed into the couplings, the pipe is given various bending, torsional, flanging and compression tests in a hydraulic machine. If the weld breaks the pipe is scrapped. Lap-welding is now applied to larger pipe up to a maximum length of 15 to 18 ft., and a diameter of 20 in. Test pressures vary from 300 to 3,000 lb. per square inch. In the larger sizes the maker's name is rolled into the pipe, and in the smaller sizes it is stenciled upon the pipe. Boiler tubes are tested under the drop hammer by end-on blows.

In butt welding, the edges of the plate are left square. The skelp is heated to the welding point and is then drawn through a bell-shaped die, the diameter of which is a little less than that of the skelp. The pressure thus induced squeezes the edges together and makes a perfect weld. The smaller pipes are generally fitted with screwed flanges and couplings. Nothing is required in the interior of the pipe in butt welding.

The attainment of the proper temperature during the drawing process is vital to the success of the work. The larger pipes must be kept moving during butt welding to prevent sagging. There is a tendency for scale to run to the bottom and cause corrosion in butt-welded pipe. At the works of the National Tube Co. a method of overcoming this trouble has been developed for pipes up to 4 in. in diameter. The pipe is passed through rolls which pull it enough to loosen the scale, which then drops off. This treatment is of great value when a pipe is to be galvanized and has a future outlook, which is worth bearing in mind.

Anthracite coal shipments in the United States in the first seven months of 1912 were 40,330,7[illegible] tons, against 40,11[illegible],048 tons in the second year of 1911. The total production for the latter year was about [illegible] tons.

ROAD MAINTENANCE SYSTEMS AND METHODS.*

By M. O. Eldridge,
Ass't in Road Management, U.S. Office of Public Roads.

THERE is no phase of the road subject which is more important than that of maintenance. The impression is quite general throughout this country that there are certain types of roads which are permanent. This is a mistaken idea. No permanent road has ever been constructed or ever will be. The only things about a road which may be considered permanent are the grading and the concrete culverts and bridges, and even they may not be lasting.

Roads constructed by the most skilful and experienced highway engineers will soon be destroyed by the traffic, the frost, the rain and the wind unless they are properly maintained, but the life of such roads may be indefinitely prolonged by continuous and systematic maintenance. Even a poor road may be greatly improved by proper maintenance. In other words, a poor road with proper maintenance may become better, in time, than a good road without it. Damage to a road from traffic or weather may be repaired at its inception with a slight expenditure of time and money, but if allowed to go on without attention for a considerable length of time it will involve a heavy outlay for repairs, and even threaten the existence of the road.

Systems of Maintenance.—There are several systems of maintenance in use in this country, among which may be mentioned the intermittent system, the patrol system and the gang system. Under the intermittent system should be included the working of certain roads by toll-gate companies, and the maintenance of roads by contract and by citizens in working out their property and poll taxes. Under the patrol and gang systems should also be included the combination of the two systems.

The intermittent system is that under which roads are repaired or maintained spasmodically once or twice a year. This is the system, or rather lack of system, which has prevailed throughout the United States until within the past few years, and needless to say it is the one under which the poorest results have been secured.

There may be some reason for toll roads, but, on the whole, this system is un-American, contrary to the spirit of our free institutions, and has been found unsatisfactory. The reason for this is that the tax is too direct and burdensome to be borne by the road users alone.

The contract system has been used to some extent in various states, but has not been found entirely satisfactory. As a general rule, the work is let to the lowest bidder. The amount paid for the work is small, and such poor service is rendered by the contractors that in many cases the roads have become worse rather than better. Under proper engineering supervision and inspection, and with plans, estimates and specifications prepared in advance, the contract system of maintenance might prove as efficient and economical as in construction work.

Under the personal service or labor tax system no state, county, town or township has ever built or kept in repair a system of first-class improved roads. This system is not applicable to any class of road work, with the possible exception of earth road dragging, in sparsely settled portions of the country. The principle of working out the road taxes is unsound, unjust and wasteful, and the results obtained under it are unsatisfactory in many particulars. During the past few years many of the states have abandoned this method. It was abolished in France about 125 years ago. It is estimated that of the eighty million dollars spent on roads in the United States in 1904, approximately thirty million dollars was worked out, whereas, in 1913, of approximately one hundred and eighty-six million six hundred thousand dollars spent on roads, only about fifteen million dollars was worked out.

The patrol system is that which provides for the permanent employment of skilled laborers or care-takers, each of whom has charge of a particular section of road.

The gang system provides for the employment of a corps of skilled laborers, who may be assigned to any part of a county, township or town where the work is most needed. This system is particularly effective for bituminous-macadam repairs.

The patrol system has been used very successfully in France for over one hundred years, and there is no doubt that it would give satisfactory results in many of the most densely populated sections of this country. It has been used to some extent in Maine, New York, Massachusetts, Maryland, New Hampshire, Connecticut, Rhode Island, Pennsylvania, and in a few counties in various other parts of the country. Men who are constantly employed in this way become experienced in their particular lines of work. They soon learn to do the work well, and will take pride and interest in it. There is no doubt that in certain kinds of maintenance operations one man will accomplish more and better results in 313 days than 313 men will accomplish in one day.

The ideal system would appear to be a combination of the patrol and gang systems whereby the patrol men or caretakers look after their particular sections of road during certain seasons of the year, and at other times work together in small gangs. A parallel to this system is found in the maintenance-of-way departments of our great railways. These provide patrolmen and track walkers who look after small defects, and section gangs to do the work which requires more than one man's services.

The assignment of caretakers or patrolmen should be left entirely to the engineer in charge. In this way the system may be rendered more elastic and more efficient.

It would be impossible to adopt the patrol and gang system everywhere throughout the country, on account of sparse population and limited resources, but there are many communities in which it might be used. It is difficult to find a community which is so poor that it could not afford to employ eight or ten laborers and three or four teams continuously, and there are thousands of towns, townships and counties which could afford ten times such a force. That such a plan would be more efficient than the intermittent systems would appear to be self-evident.

In dealing with the subject of maintenance aside from its administrative features, the only wise and safe plan is to provide, after making careful estimates, for a cash appropriation sufficient to maintain every mile of new road constructed. Funds should also be provided for taking care of the old roads. These appropriations and expenditures should be kept absolutely separate from the construction fund, and if it is possible to do so the maintenance funds and the repair funds should also be separated. If a community can not afford to set aside a fixed and adequate sum for the maintenance of a high-class road, then it is doubtful whether it can afford to build such a road.

*Paper read at Maine State Road Convention at Bangor, April 8th, 1914.

Methods of Maintenance.—The methods to be employed under any system will vary with the type of road to be maintained and the character of traffic. To deal with these phases of the subject in a satisfactory manner would require more time and space than can be devoted to it in a short paper. This part of the subject will, therefore, be confined to a few brief suggestions regarding the best methods of maintaining earth, gravel and macadam roads.

Earth Road Maintenance.—The first and last commandment in earth road maintenance is to *keep the surface well drained.* To insure good drainage the ditches should be kept open, all obstructions removed and a smooth crown maintained. Except for very stony soil, the road machine or scraper may be used very effectively for this work. The machine should be used once or twice a year, and the work should be done when the soil is damp, so that it will pack and bake into a hard crust. Wide and shallow side ditches should be maintained with sufficient fall and capacity to dispose of surface water. These ditches can in most places be constructed and repaired with a road machine.

All vegetable matter, such as sods and weeds, should be kept out of the road, as they make a spongy surface which retains moisture. Clods also are objectionable, for they soon turn to dust or mud, and for that reason roads should never be worked when dry or hard. Boulders or loose stones are equally objectionable if a smooth surface is to be secured.

A split-log drag or some similar device is very useful in maintaining the surface after suitable ditches and cross-section have once been secured. The drag can also be used on a gravel road just as effectively as on an earth road. The principle involved in dragging is that clays and most heavy soils will puddle and set very hard when wet. The essential requisite, therefore, is that the work be done at the proper time. This is the point which seems to be the hardest to impress on the average man. The little attention that the earth road needs must be given promptly and at the proper time if the best results are to be obtained.

In dragging roads only a small amount of earth is moved, *just enough* to fill the ruts and depressions with a thin layer of plastic clay, which packs very hard, so that the next rain, instead of finding ruts, depressions and clods in which to collect, runs off, leaving the surface but little affected.

The drag should be light and should be drawn over the road at an angle of about 45 degrees. The driver should ride on the drag and should not drive faster than a walk. One round trip, each trip straddling a wheel track, is usually sufficient to fill the ruts and smooth out the surface. If necessary, the road should be dragged after every bad spell of weather, when the soil is in proper condition to puddle well and still not adhere to the drag. If the road is very bad it may be dragged when very wet and again when it begins to dry out. A few trips over the road will give the operator an idea as to the best time to drag. Drag at all seasons, but do not drag a dry road. The road will freeze smooth if dragged just before freezing weather.

The slope or crown should be maintained at about one inch to the foot. If the crown becomes too high it may be reduced by dragging toward the ditch instead of from it. If the drag cuts too much, shorten the hitch and change your position on the drag. If it is necessary to protect the face of the drag with a strip of iron, it should be placed flush with the edge of the drag and not projecting. A cutting edge should be avoided, as the main object in dragging is to *smear* the damp soil into position. The dragging of roads may be encouraged by offering to caretakers or patrolmen special bonuses or prizes for the best mile of road.

Maintenance and Repair of Gravel and Stone Roads.—The following suggestions may be found useful in the maintaining of gravel and stone roads. Culverts and ditches should be carefully inspected at frequent intervals and all obstructions removed. If the weeds are cut from shoulders and ditches grass will soon take their place. Whenever a mile of new stone road is constructed the contractor should be required to place about 100 tons of 1½-inch stone (ordinarily referred to as No. 2 stone) and screenings at convenient places for maintenance and repairs. During the summer months stone chips only should be used for patching.

The rake is one of the most useful tools used in stone or gravel maintenance. Large patches of stone or gravel should not be spread over the whole road at one time, especially in dry weather. All repairs should be made before cold weather, so that the road will consolidate and go through the winter in good condition. The best time, however, to patch stone and gravel roads is in the spring of the year. The spring showers will aid the traffic in consolidating the materials.

Before applying new material, all projecting stones should be removed and the surface slightly roughened with a pick. In applying new material thick layers should be avoided. One stone deep is ordinarily thick enough, and no stone used for repair work should be larger than two inches in diameter, and the size should be smaller for patch-work.

Trap rock, granites and other hard rocks should be broken finer for repair work than limestones and other softer rocks. Never crack stones on a road if you desire to secure a smooth surface. A thin layer of screenings, preferably trap rock, applied to a gravel road will produce a wearing surface almost equivalent to macadam.

Newly laid stone for patch-work or repairs should be bonded with screenings or a good quality of gravel. An excess of binder, however, should be avoided. In cutting away the worn out material for gravel and stone road shoulders all road scrapings, horse droppings and other rubbish should be kept off the road. Such materials will ruin the best road ever constructed.

The caretaker should never neglect an opportunity to remove loose stones from the road surface. Loose stones or water-worn pebbles should not be used for repairs or maintenance, as they will not bind.

Earth should not be used for patching stone or gravel roads, for earth turns to dust and after the first rain dust turns to mud. A mud blanket over the road will prevent it from drying out and hasten its destruction. The middle of the road should always be a little higher than the sides so that it will shed water quickly. This crowning, however, should not be carried to such an extreme that vehicles are forced to use the centre of the road only, thus confining the wear to two wheel tracks.

If the road is so badly worn or rutted as to require re-building the best practice is to roughen the surface with a scarifier drawn by a roller, or by means of spikes placed in the driving wheels of the roller. The surface is then harrowed and all large stones removed. After bringing the surface to the proper crown and cross-section a layer of No. 2 stone is applied, bonded with screenings, sprinkled and rolled in the same manner as for the original construction.

LOCATING LEAKS IN WATER MAINS BY MEANS OF THE WATER HAMMER DIAGRAM.*

By Melvin L. Enger,
Assistant Professor of Applied Mechanics, University of Illinois

WHEN the valve at the end of a long pipe line is closed suddenly, great pressures may be caused. The term water hammer has been applied to this phenomenon. If the valve could be closed instantly all of the water in the pipe would not be stopped at the same instant. The layer nearest the valve would stop first, then the next layer and so on until the impulse has travelled through the entire pipe line. As each layer of water is brought to rest its pressure will, of course, be increased. The velocity of the transmission of the pressure wave will be the same as the velocity of transmission of sound in the water in the pipe, and will vary between 3,400 and 4,700 ft. per sec., depending upon the material of the pipe and upon the ratio of the thickness to the diameter of the pipe.

It has been found that for any given pipe, the amount of the water hammer pressure is a constant times the extinguished velocity. The value of this constant (also called the water hammer coefficient) varies directly with the velocity of transmission of the pressure wave, and for cast-iron pipe used for water supplies has values between 45 and 63. For cast-iron pipe between 6 and 16 inches in diameter, the average value of the constant is about 55. That is, the water hammer pressure caused by the sudden closure of a valve at the end of a long pipe line, in pounds

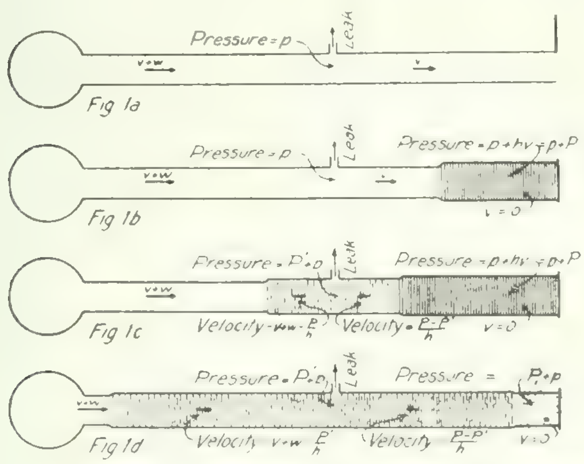

Fig. 1.—Condition of Pressure and Velocity at Various Times After Closing the Valve.

per square inch, is 55 times the velocity of the water in the pipe before the valve was closed, in feet per second.

Fig. 1a represents a pipe line in which there is a leak. The flow between the source (reservoir or large pipe) and the leak is $v - w$ feet per second, and between the leak and the valve is v feet per second. Fig. 1b shows the conditions in the pipe line a short time after the valve at the end is suddenly closed. The velocity of the water near the valve has been extinguished and its pressure increased hv lb. per sq. in. (h being the water hammer coefficient). If the distance from the valve to the leak is l feet and the velocity of propagation of the pressure wave is Z ft. per sec., the pressure wave will reach the leak l/Z seconds after the valve closed. Since the original pressure at the leak allowed a quantity of water equal to Aw cu. ft. per sec. to escape, it is evident that a higher pressure will cause a greater quantity to flow. The extinguished velocity between the leak and the source will, therefore, be less than v ft. per sec. Hence the water hammer pressure generated in this part of the pipe line will be less than hv lb. per sq. in. A wave of reduced pressure will therefore travel from the leak toward the valve. Fig. 1c shows the conditions a short time after the pressure wave has passed the leak. The wave of reduced pressure will reach the valve $2l/Z$ seconds after the valve closed. Fig. 1d shows the conditions a short time after the wave of reduced pressure has reached the valve.

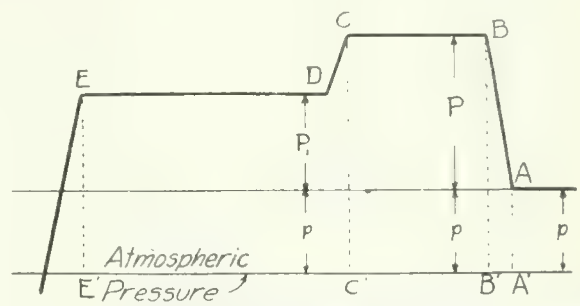

Fig. 2.—Typical Water Hammer Diagram Showing Effect of a Leak.

The water hammer diagram is a graphical representation of the pressure in the pipe line near the valve for a time after the valve is closed. In the experiments made by the writer the diagram is obtained by having the pencil of an indicator trace on a sheet of paper wrapped around a drum driven at a uniform rate by an electric motor. Another pencil attached to an electro-magnet makes a time record.

Fig. 2 shows the characteristic features of a water hammer diagram taken at the end of a pipe line in which there is a leak. The first rise of pressure as the valve begins to close is shown at A. The indicator pencil reaches B when the valve is fully closed. The pressure then remains practically constant until the effect of the leak is registered at C. The distance A'C' represents the time required for the pressure wave to travel from the valve to the leak and back to the valve. If the velocity of transmission of the pressure wave is known, the distance from the valve to the leak is easily computed. The difficulty in the use of this method is in the determination of the velocity of transmission (Z) of the pressure valve. The velocity of the pressure wave will vary somewhat, according to the amount of air in the water. Another method which avoids the necessity of determining the value of Z is as follows: When the indicator pencil reaches E, the first relief of pressure due to the source is felt. The distance A'E', therefore, represents the time required for the pressure wave to travel from the valve to the source and back to the valve. If the length of the pipe line from the valve to the source is L, the distance from the valve to the leak can be determined by proportion.

$$l : L :: A'C' : A'E'$$

In the writer's experiments, much more consistent results were obtained by this method than by the use of the velocity of transmission of the pressure wave and the time required for the pressure wave to go from the valve to the leak and return, as scaled from the diagram.

The quantity of water discharged from the leak can also be determined from the water hammer diagram. The

*From paper read before the Illinois Water Supply Association, March, 1914.

expression for the velocity of flow in the pipe due to the leak is:

$$v = \frac{\dfrac{P - P_1}{h}}{\left[\dfrac{P + P_1}{2p} - 1\right]^{0.5} - 1}$$

P is the amount that the pressure is increased due to water hammer, P_1 is the amount that the pressure at the valve is above the original pressure after the return wave from the leak reaches the valve; p is the original pressure at the valve; h is the water hammer coefficient.

The following values are taken from experiments made by the writer in 1906. The last two were measured from the second diagram shown in Fig. 4.

Calculated Distance. Feet.	Actual Distance. Feet.
64	72
70	72
371	381
385	381
375	381
262	265
295	265
110	113

A number of values have been computed from the equation, and the results have been plotted in Fig. 3. It was assumed that $P = 55$ lb. per sq. in., $p = 40$ lb. per

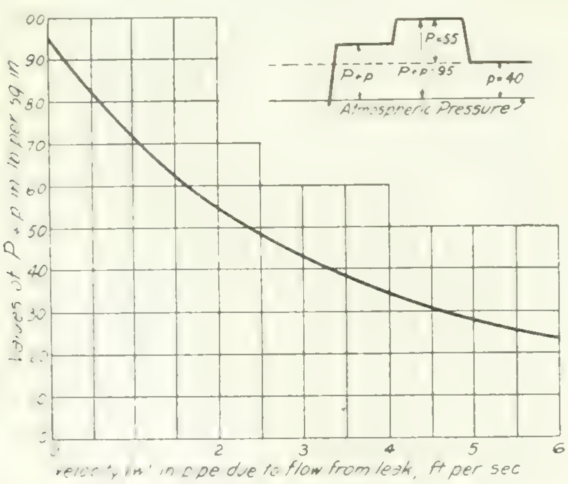

Fig. 3.—Pressure Drop on Water Hammer Diagram Due to Leaks of Various Amounts.

sq. in., and that $h = 55$. It will be seen from an examination of the curve that even small leaks will produce a noticeable fall of pressure on the water hammer diagram.

The first suggestion that the water hammer diagram could be used to determine the location of a leak was made by Professor Joukovsky as the result of a series of experiments made in 1897 and 1898 for the waterworks department of Moscow, Russia. He published a monograph (Stoss in Wasserleitungsrohren) in 1900. A translation of this paper, somewhat modified, was published in the Proceedings of the American Waterworks Association in 1904. Experiments were made by the writer in 1906 on a 2-inch pipe 730 feet long in the Hydraulic Laboratory of the University of Illinois. Fig. 4 shows two diagrams taken at that time.

In using this method for determining the location of a leak, the following suggestions are made. The quick-closing valve should be at the end of the section of pipe to be tested. This can be accomplished by tapping the main close to a valve, the valve in the main being kept closed during the experiments. The pipe leading from the main to the quick-closing valve must be large enough that a water hammer pressure at least as great as the static pressure can be caused by the sudden closure of the valve. The indicator should also be connected at this point of the main, or to the pipe containing the quick-closing valve. If possible, the method of proportional distances should be used. The distance to the source

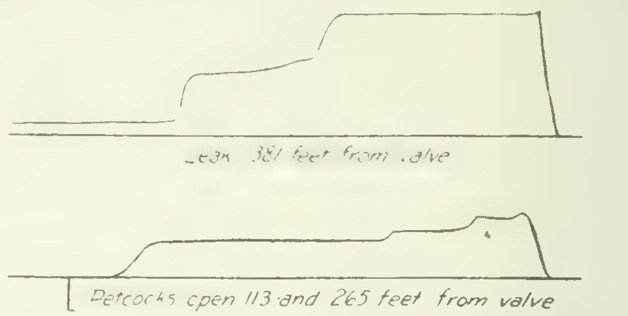

Fig. 4.—Water Hammer Diagram, Showing Effect of Leaks, Taken on a 2-in. Pipe Line, 730 Feet Long.

(large main) should be measured. A hydrant partly open will make a good reference point in case the main on which the experiments are being made is very long. When the method of proportional distances is used it is not necessary to know the speed of the paper. It is only necessary that the paper travel at a uniform speed while the diagram is being taken.

An apparatus called the "pulsograph," using the above principles for locating leaks, has been patented. It was described before the meeting of the New England Waterworks Association in September, 1913.

CONCRETE MATERIALS.

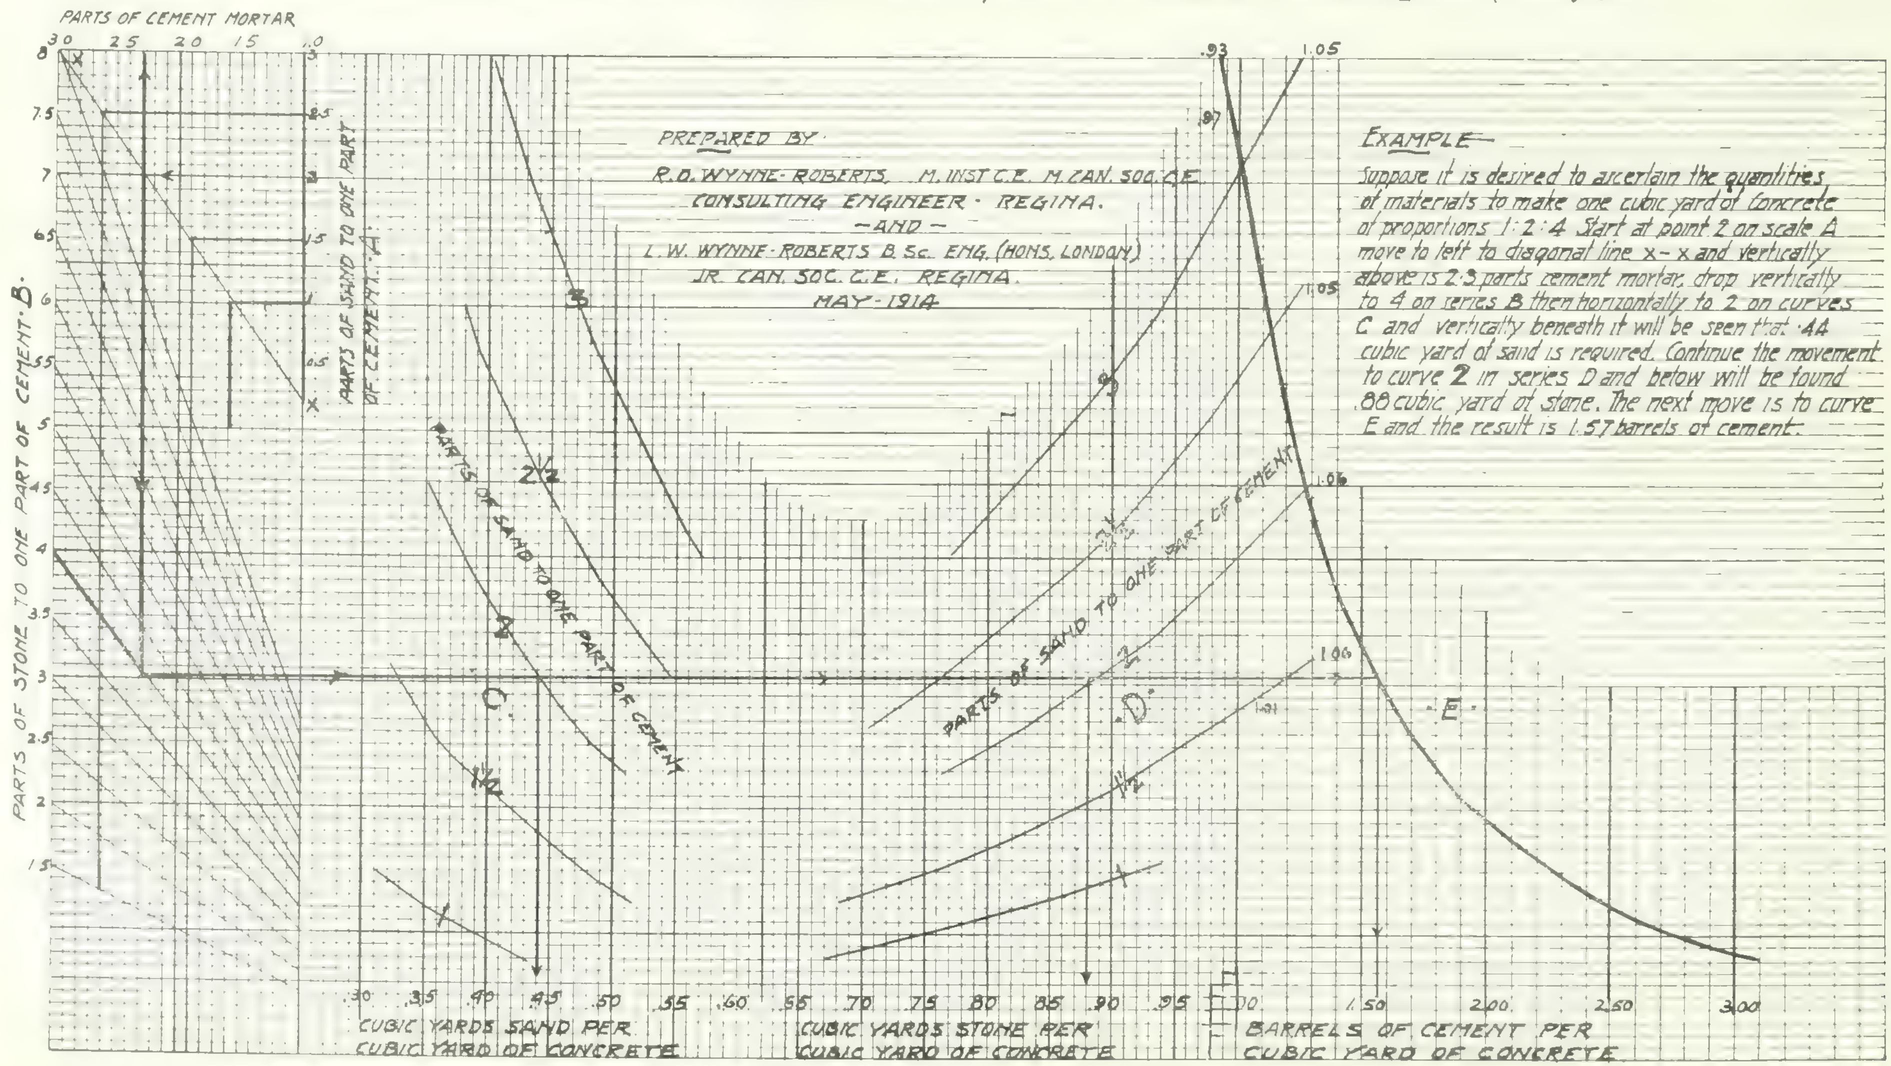
By R. O. Wynne-Roberts, Regina.

THOSE who have frequent occasion to prepare the estimated cost of concrete structures find it useful to have data as to the quantities of materials that are required to make one cubic yard of concrete of different proportions. There are tables given by various authors which are convenient for office use, but volumes are seldom carried about and consequently calculations, even approximate, are usually deferred until the engineer returns to his office. The author has experienced a need for a diagram which will afford the information as to the quantities of cement, sand and stone necessary per cubic yard of concrete in place and set to build one. The accompanying diagram is believed to be very simple and easily understood, and is applicable for concretes whose proportions range from 1:1:1½ to 1:3:8, which will doubtless suffice for practically all classes of work. The curves are derived mostly from tables in Taylor and Thompson's book on concrete and therefore no claim is made for originality of data, but the diagram is original. It is hoped it will be found useful by readers of *The Canadian Engineer*. In the top left-hand corner is given the volume of cement mortar produced by mixing various proportions of cement and sand. When any proportions of

cement, sand and stone are specified all that is necessary is to start on scale A with the given number for sand, trace that line to the left as far as the diagonal line X—X, then move vertically downward until the line crosses the sloping line giving the number for stone, and afterwards move to the right, intersecting the given sand volumes in series C and D and also the curve E, and vertically beneath each intersection will be found the quantities of sand, stone and cement respectively. An example is given in the diagram to show how the quantities of concrete ingredients for a proportion of 1:2:4 are found.

DIAGRAM FOR OBTAINING QUANTITIES OF MATERIALS REQUIRED PER CUBIC YARD OF CONCRETE.

Based on Barrel of Cement of 3.8 Cubic feet, and 45 per cent voids in broken stone and gravel. (average)



Coast to Coast

Oak Bay, B.C.—A lifting plant for sewage is being installed at Oak Bay, B.C.

Weston, Ont.—The sewerage system and sewage disposal plant at Weston have been formally opened.

Fort William, Ont.—Work on the constructing of the belt line route for the street railway at Fort William is in progress.

Winnipeg, Man.—It has been reported that the Manitoba Government elevator system has been acquired by United States interests.

Port Arthur, Ont.—The Port Arthur council has passed a by-law placing the money required in 1914 for general purposes at $300,210.40.

Saskatoon, Sask.—Money by-laws for the raising of $271,512 were passed at Saskatoon, being principally for additions to sewer and water systems.

Oxbow, Sask.—The municipality of Oxbow is considering and examining into the matter of installing an electric lighting plant for the town.

Edmonton, Alta.—All the by-laws which were voted on by the burgesses on April 6th have been given their third reading and finally passed by council.

Hamilton, Ont.—The proposal to construct a temporary sewage system in the eastern section of Hamilton has been dropped by the works committee of the city council.

Regina, Sask.—The Dominion Government has created a Saskatchewan headquarters for its electricity inspection branch of the Department of Inland Revenue at Regina.

Toronto, Ont.—The ratepayers of North Toronto have endorsed the proposed sewerage scheme for North Toronto as outlined by the engineers of the civic works department.

Winnipeg, Man.—To accommodate non-resident contractors, the board of control of Winnipeg has arranged to extend the time limits for receiving tenders for various kinds of work.

Saskatoon, Sask.—The city council has decided to resubmit the by-laws which were defeated at the polls. The most important one provides for $200,000 for power house extensions.

Ottawa, Ont.—Chairman Drayton of the railway commission has stated that he will take immediate steps to have the bridge on the York and Scarboro townline rebuilt without delay by the C.P.R.

Edmonton, Ont.—It has been reported that it is not unlikely that steps may be taken to establish a municipal paving plant at Edmonton. $35,000 is appropriated for this purpose, and it has never been used.

New Toronto, Ont.—A proposal for installing a waterworks system at New Toronto is under consideration by the municipality. It is proposed to take water from the lake, and also to construct a mechanical filtration plant.

Weyburn, Sask.—Money by-laws, amounting to $155,500, have been endorsed by the ratepayers, and work will proceed at once on the improvements concerned, which consist of extensions to sewers, waterworks and electric plant.

Carlyle, Sask.—Construction on the large municipal electric lighting system has commenced and will be carried to completion without undue delay. Messrs. Smith Electric Company, of Melville, have the work of installation in hand.

Toronto, Ont.—The total amount of revenue collected by the civic waterworks department for the term just ended, has been announced as approximating $450,000, or $50,000 more than was received during the corresponding period last year.

Port Arthur, Ont.—The agricultural and good roads committees of the Port Arthur board of trade have received information to the effect that $150,000 will be expended by the government on the roads of the surrounding district during the ensuing season.

Toronto, Ont.—The Ontario government has approved the 1914 programme of road and bridge construction for the County of York, and it is announced the work will commence immediately after the by-law authorizing expenditure has been altered to the extent of $300,000, instead of $100,000 as it now stands.

Redcliff, Alta.—The Redcliff Light and Power Company has commenced work preparatory to drilling the seventh gas well at Redcliff. It is located in the industrial section, and is expected to strike the gas at 1,200 feet. Gas is furnished to manufacturers at five cents per thousand, and power at $2.40 per h.p. per year in Redcliff.

St. Thomas, Ont.—Recently the value of the St. Thomas waterworks plant and system has been appraised by representatives of the Canadian Appraisal Company. The report submitted places the present value of the plant at $513,829, and the estimated cost for replacing the same at $577,992.32, thus allowing for a depreciation of $64,163.32.

Yorkton, Sask.—The Pas board of trade has written the Yorkton board of trade urging the endorsation of a resolution calling on the government of Canada to adopt means to compel railways now holding charters for branch lines connecting them with the Hudson Bay road to commence construction of the same under penalty of having said charters revoked.

Vancouver, B.C.—The civic board of works of Vancouver has adopted the list of new local improvement work amounting, with that already begun during 1914, to $1,400,935. The list as passed represents the limit of expenditure which the city may incur in this line at the present time. New work not yet formally approved by the board of works totals $104,972.

Victoria, B.C.—Messrs. Parks, Tupper, and Kirkpatrick, contracting firm for the government work at Soughees Reserve, has commenced work and expects to complete the contract by the end of June or early in July. The contract calls for the erection of a creosoted pile wharf, over 600 feet in length and 50 feet in width, and for the excavation and levelling off of approximately 27,000 cubic yards of material.

Calgary, Alta.—It has been announced by Dr. Ings, managing director of the Elbow River Power and Development Company, that the company will commence this fall the building of an electric railway which is to connect Calgary with Springbank and Jumping Pond. The line will be about 40 miles long, and will not take more than 5 or 6 months to construct. It will be known as the Elbow Suburban Railway.

Quebec, Que.—New plans have been deposited by the G.T.P. Railway company in the Quebec registry office which provide for a change in the site of the tunnel proposed to be constructed under the rock of Quebec. It will have an entrance in the vicinity of where the Dufferin Terrace passenger elevator is situated and will extend under the city and under the Laval University, with an exit at the foot of Damboruges street.

Winnipeg, Man.—The following summary of total expenditure on Winnipeg hydro-electric system up to the end of February, 1914, has been published: water power construction, $3,414,175.99; distribution system, $2,357,936.96; H. E. S. extension, $130,761.81; conduit system, $321,102.08; discount and express on sale stock and debentures, $174,495.52; water power and joint use of poles, $13,161.09; total expenditure, $6,628,068.97.

Fort William, Ont.—The commencement of construction on the 2,646-foot sea wall at the mouth of the Mission river is well under way. All of the timber for the cribwork has arrived from British Columbia and no interruption is anticipated until the contract has been completed. Three cribs, each 120 feet long, are in the water ready to be placed in position as soon as dredging has been completed to the depth required for sinking the cribs.

Victoria, B.C.—An agitation is on foot at Victoria to hasten the bridging of Seymour Narrows. It is planned that a special committee will take in hand the forwarding of the project, and that the committee shall send a delegation to Ottawa at the earliest possible date to urge the importance of the commencement of the work; also that all the various municipalities and associations interested be asked to send delegates to Ottawa with the Victoria delegation.

Leaside, Ont.—Construction is commencing at Leaside upon the factory building for the Canada Wire and Cable Company, to be erected at a cost of about $1,000,000. It is said that the structure will be one of the longest factory buildings in the Dominion. One section will be 500 feet in length and 3 stories in height, while the rest of the building will be one story. Already the most of the brick foundation has been laid, and a compressed air plant is being installed, so that the steel construction may be undertaken.

Medicine Hat, Alta.—The city engineer's report for the month of April shows that at Medicine Hat the high-pressure mains of the natural gas system were extended 1,500 feet; the water distribution system was prolonged by 3,863 feet of 6-inch pipe; 2 miles of domestic and storm sewers were laid; 3 miles of 6-foot cement sidewalk, 2,250 square feet of street crossings and 432 square feet of lane crossings were constructed; and in the electric light department about 2 miles of lines were erected.

Ottawa, Ont.—It has been reported at Ottawa that a movement is being made by the Hon. Robert Rogers to provide for an increase in the Government subsidy allotted to the construction of drydocks. This action is being taken so as to encourage these constructions to be of the first class. The present act provides for a subsidy of 3½ per cent. per annum of the cost of the drydocks for 35 years, where the expenditure is over $1,000,000. The Government now proposes to increase the subsidy to 4 per cent. per annum.

London, Ont.—London has already embarked upon pavement construction work for 1914 which will entail an expenditure of $100,000. Work on contracts amounting to $25,000 is now in progress, and tenders have been called for the Wortley road pavement, to cost $35,000. Pavements costing $40,000 in all will be laid during the summer on various other streets and roads of the city. Asphalt pavements with concrete bases will be laid in the majority of cases, although vitrified brick and other pavements will be tried in various sections.

Sault Ste. Marie, Ont.—The International Joint Commission has approved the joint applications of the Michigan Northern Power Company of Sault Ste. Marie, Mich., and the Algoma Steel Corporation of Sault Ste. Marie, Ont., to erect compensating works at a point in the St. Mary's River between the two cities. The approval has been given upon certain conditions, with respect to the construction of the works which have been recommended by the Government engineers of the U.S. and Canada, and also upon conditions governing the works after construction.

Moose Jaw, Sask.—By-laws are being advertised at Moose Jaw to provide for the raising of $12,985 for the extension of the city's waterworks through River Park and Wellesley Park; to provide $35,000 for construction of cement sidewalks with curb and gutter; $12,000 required to complete street paving; $106,761.78 for extension of sanitary sewers through various portions of the city; $155,000 for extensions to the electric light and power system; $17,015 for the extension of sanitary sewers in River Park and Wellesley Park; $18,700 to pay the deficiency of moneys on civic works previously undertaken; and for $73,238.22 for extensions to the civic waterworks system.

Amherst, N.S.—A great deal of bridge work is contained in the program of construction to be carried out this year on the Intercolonial Railway. 105 light steel bridges will be strengthened so as to accommodate heavy power from Truro to River du Loup, and already contracts for 40 have been awarded to various bridge contracting companies in Canada. The Rhodes, Curry Company, of Amherst, N.S., have secured contracts from the Dominion Government for 9 girder bridges; and the steel that will be used is to be imported in channels and fabricated at the shops of the Canadian Car and Foundry Company, of Amherst.

Montreal, Que.—The surplus earnings of the Montreal Light, Heat, and Power Company, or earnings available for dividend purposes, for the year ended April 30th, will be over $3,000,000, or what will mean a rate of close upon 18 per cent. The percentage of the previous year was 15.9. An idea of the growth of the company is afforded by a reference to the company's record. Gross earnings before operating and maintenance expenses and fixed charges were below the $3,000,000 mark in 1904. The company is now earning more for dividends than it took in in gross receipts nine years ago. This has been accomplished in the face of a steady reduction in both electric and gas charges to its consumers.

Ottawa, Ont.—It is reported that there will be an overdraft amounting to several thousands of dollars this year in the Ottawa city waterworks department. The appropriation for the department for the year is $153,000. In January the expenditure was $35,860; February, $12,006; March, $16,606; April, $12,504; the total amount spent to the end of last month being $76,979. The total expenditure up to end of April last year was $63,536. The increase is due to the fact that this year the waterworks department has a number of additional expenditures, including the maintenance of the booster plant and the wells, and the cost of the new intake pipe. However, the department hopes to keep the expenditure for the twelve months within $155,000.

Ottawa, Ont.—According to the statement of Sir Donald Mann, recently published at Ottawa, the C.N.R. line now under construction from Ottawa to Port Arthur, via Pembroke, Eastport, North Bay and Sudbury, will be put in operation for freight and local traffic some time next fall. With the completion of this line from Ottawa to Port Arthur the C.N.R. will have a through line in operation from Quebec to British Columbia, passing through Montreal, Ottawa, Pembroke, North Bay, Sudbury, Winnipeg and most of the large and important centres in the West. Ottawa will be the junction point on this transcontinental line for the line to Toronto and on through Parry Sound, joining the main line again at Capreol, a comparatively short distance west of Sudbury.

Montreal, Que.—Active work is now in progress on the general plan of improvements along the Montreal harbor front. The main works so far are at the Victoria pier, where the old wooden pier has been removed and the site is being dredged out to make place for a modern concrete jetty, while there will also be put in a new pier 1,800 feet long. Similar work is being done at Section 27, where the old wooden pier is being replaced by a concrete jetty. Work is also being done filling in the space between the Canadian Vickers Company's drydock and the shore. All the gas and spar buoys, as well as the lightships, have been placed in Lake St. Louis. [illegible]

lights and aids to navigation on the Lachine Canal and Lake St. Louis had been completed.

Victoria, B.C.—The work of laying a 12-inch main to connect the Gorge Road main with the temporary pipe line over the Gorge, through which the city is now securing its supply from the system of the Esquimalt Waterworks Company, has been completed. The new main will provide for an additional supply approximating 1,000,000 gallons per day and bring the total supply available from the Esquimalt Waterworks Company to slightly below 6,000,000 gallons per diem. By next fall the pipe line of the Sooke system will be laid from the city to a point beyond Parson's Bridge. When this is done a permanent connection with the system of the Esquimalt Waterworks Company will be made at the bridge, and at any future time, if accident should interfere with the Sooke supply, instant connection with the company's system will be possible.

Halifax, N.S.—Mr. Thomas Cozzolino, president of the Nova Scotia Construction Company, Limited, stated recently in connection with the work being done by his company on the Dominion Atlantic section of the C.P.R., that in constructing No. 2 pier at the north end of the Halifax harbor 1,600 concrete piles had been sunk, each from 58 to 78 feet in length and weighing as much as 75 tons. These were driven into the bottom of the harbor, where the water is from 38 to 40 feet deep by a hammer weighing about 16 tons. About 300 more of these piles will be driven, making a total of about 2,000. Mr. Cozzolino state that experts aver that this piece of work has formed the solution of the concrete pier problem. The wharf will be 800 feet in length, and will cost, when completed in August, about $1,000,000. Concrete sheds of the finest construction are also called for in the plans for the work being carried out at this port.

Winnipeg, Man.—W. E. Skinner, consulting engineer, recently gave an interesting talk on the hydro-electrical resources of Manitoba at a union of the Jovian order at Winnipeg. He stated that, according to the report made to the government on water-powers within the province, the total amount of power within the limits of the province that can possibly be developed was 3,037,355 horse-power; and in the summer months, from May to October, there would be available another 218,430 horse-power. This, Mr. Skinner pointed out, was three times as much power as was used in the cities of Chicago and New York for all purposes during last year. While much of the power in Manitoba was at present inaccessible, the resources of the country would bring it close to hand.

Fort William, Ont.—Work will soon be commenced by the Thunder Bay Contracting Company on the 2,646-foot sea wall which is to be built at the mouth of the Mission river. The first work to be done to the wall was commenced early last March, but only timber enough for the construction of three cribs was on hand; and when this was used, work was stopped until a fresh supply could be obtained from the lumber mills in British Columbia. This supply is expected to arrive this week. The wall will be built on the crib construction plan from the bottom of the river, which is 28 feet deep at that point, to the surface; and from there up the wall will be constructed of concrete. When completed, it will be the means of reclaiming several acres of valuable land from Lake Superior.

Toronto, Ont.—The Department of Colonization Roads of the Ontario government has already commenced sending road gangs throughout Northern Ontario, since this season's program of work is a considerably extensive one. A highway connecting the Transcontinental and Canadian Pacific Railways through Waubagoon township will be undertaken at once. Other roads to be constructed are a new trunk road running out of Sudbury and Conaston, one connecting Quibell and Vermillion, and the Gowganda road in the pulpwood district of Espanola. Further, the Provincial and Dominion governments have under present consideration the extension of the trunk line of roadway running between North Bay and the Soo, so as to make through connection between Ottawa and Sault Ste. Marie. The contemplated new section of this highway would follow the old military road from Ottawa to Mattawa, and thence to North Bay. The extension is being strongly urged, and it is likely that the proposal will be adopted.

Toronto, Ont.—It has been announced that early in June will commence a motor survey of Ontario to be made under the direction of the provincial highways department, the purpose of which is to furnish the basis for construction work next year upon the $30,000,000 highways system for older Ontario. The motor survey will be carried on by several corps of engineers, each with a section of the province to cover. They will determine the present condition of all the travelled roads, urban, interurban and rural. They will study local conditions with a view to finding out which should be improved and the type of construction best adapted to meet traffic requirements. Sources of road-building material will also be investigated. Upon the completion of the survey tentative schemes will be submitted to the various counties and townships with a view to arriving at permanent plans. At present, the department has engaged 12 draughtsmen on the preparation of county and township road plans, upon which the progress of construction on each type of highways will be recorded from season to season.

ZINC AND POWER POSSIBILITIES AT NELSON, BRITISH COLUMBIA.

An outcome of the efforts which have been made by the board of trade of Nelson, B.C., and of mining men of the district, to induce the Woolsey, McAlpine, Johnson Zinc Corporation of New York to locate its proposed new electric zinc smelting plant at Nelson, has been to awaken interest in the possibilities of the district. Consequently, Mr. Johnson, Dr. Struthers, his associate, and Dr. E. A. Barlow, of McGill University, Montreal, who has been working on the problem for the Canadian Federal Government, are now at Nelson going into the question of electric power supply, site and other questions.

It was on account of the success which has been achieved by the Johnson process that the Government, on the advice of W. R. Ingalls, of New York, zinc expert, discontinued its work and decided to await further results from Mr. Johnson.

Huge bodies of low-grade zinc ore, in developed and undeveloped mines of the district, await the solution of the treatment of complex zinc ores and if the process is carried to a complete success it will mean a heavy increase in mining operations in this district.

With last week's output the total production of mines in Rossland, Slocan-Ainsworth, Nelson and East Kootenay districts this year was brought to 182,837 tons. Shipments to Trail smelter last week totalled 7,030 tons, which is 804 tons greater than those of the previous week. Shipments to the smelter for the year are 117,053 tons.

The Granby Con. Co., of Anyox, B.C., is operating only one of its blast furnaces at its new works at which smelting was commenced on March 16. It is stated that experience thus far indicates that ore from the company's Hidden Creek mines, near here, can be smelted without lime flux, and that 700 tons a day is being put through the single furnace in blast.

AMERICAN WATERWORKS ASSOCIATION.

The 34th annual convention of the American Waterworks Association was held last week in Philadelphia, and was exceedingly well attended. One noteworthy feature of the meeting was the early arrival and registration of delegates, over 600 having registered before the end of the second day of the convention.

Monday was taken up largely with administrative matters. Several recommended amendments were discussed. These were adopted at the Tuesday morning session, which also included the report of the executive committee and the address of welcome of Mayor Blankenburg, and the President's annual address.

The election of officers resulted in the election as president for 1914-15, of George G. Earl, General Superintendent of the Sewerage and Water Board of New Orleans; vice-president, Nicholas S. Hill, Jr., Consulting Engineer, New York; treasurer, James M. Caird, Troy, N.Y., and trustees, Allen Hazen, Consulting Engineer, New York, and H. W. Cuddeback, Superintendent Passaic Water Company, Paterson, N.J.

The following were among the Canadian delegates present at the convention: W. H. Randall, Toronto, Ont.; Thos. Hodkinson, London, Ont.; H. Hymmen, Berlin, Ont.; Geo. K. Crocker, St. Thomas, Ont.; F. A. Dallyn, Toronto, Ont.; J. J. Salmond, Toronto, Ont.; J. D. Barnet, Stratford, Ont.; A. Milne, St. Catharines, Ont.; T. F. Matthews, Peterborough, Ont.

COMING MEETINGS.

INTERNATIONAL CONFERENCE ON CITY PLANNING.—To be held in Toronto, May 25th, 26th and 27th, 1914, in charge of the Commission of Conservation. Secretary, James White, Ottawa.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30th to July 4th, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—Summer convention to be held at Brighton Beach, N.Y., July 3rd and 4th, 1914. Secretary, J. R. Wemlinger, 11 Broadway, New York.

UNION OF CANADIAN MUNICIPALITIES.—Annual Convention to be held in Sherbrooke, Que., August 3rd, 4th and 5th, 1914. Hon. Secretary, W. D. Lighthall, Westmount, Que. Assistant-Secretary, G. S. Wilson, 402 Coristine Building, Montreal.

AMERICAN PEAT SOCIETY.—Eighth Annual Meeting will be held in Duluth, Minn., on August 20th, 21st and 22nd, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

CANADIAN FORESTRY ASSOCIATION.—Annual Convention to be held in Halifax, N.S., September 1st to 4th, 1914. Secretary, James Lawler, Journal Building, Ottawa.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal.

CONVENTION OF THE AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—To be held in Boston, Mass., on October 6th, 7th, 8th and 9th, 1914. C. C. Brown, Indianapolis, Ind., Secretary.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9th to 13th, 1914. I. S. Pennybacker, Executive Secretary, and Chas. P. Light, Business Manager, Colorado Building, Washington, D.C.

PERSONALS.

CHAS. F. LAW, of Vancouver, is in charge of location work for the proposed Pacific, Peace River and Athabaska Railway.

D. W. HOUSTON has been appointed superintendent of the Regina Street Railway. Since the resignation of H. Doughty he has been acting superintendent.

W. C. BRENNAN, of Hamilton, has been appointed street commissioner for the city of Fort William, Ont. Mr. Brennan was at one time street commissioner of Hamilton, Ont.

WILFRED P. BRERETON, B.A.Sc., '03, of the University of Toronto, who was formerly connected with the Power Construction Department of the city of Winnipeg, and who has also been connected with much engineering work in Toronto and Hamilton, was appointed, on May 19, city engineer of Winnipeg.

PAUL E. MERCIER, B.A.Sc., Am. Can. Soc. C.E., of Baulme and Mercier, consulting engineers, Montreal, was recently appointed assistant engineer to the city of Montreal. Mr. Mercier, who was formerly resident engineer at Quebec for the Department of Public Works, and also a constructional engineer for the Transcontinental Railway, will assume his new duties in a few days.

OSCAR B. MUELLER, president and general manager of the H. Mueller Manufacturing Company, Limited, of

Sarnia, Ont., was elected president of the American Waterworks Manufacturers' Association.

M. P. BLAIR, city engineer of St. Boniface, Man., and C. L. HUFF, town engineer of Athabasca, Alta., have been transferred from associate members to members of the American Society of Civil Engineers. FRED. L. MACPHERSON, municipal engineer of Burnaby, B.C., A. R. MOORE, resident engineer, Kettle Valley Railway, Kelowna, B.C., and W. W. SMITH, assistant engineer, Grand Trunk Railway, Montreal, have been elected associate members.

OBITUARY.

The death occurred last week of William Wainwright, Sr., vice-president of the G.T.R. and G.T.P. Mr. Wainwright had attained the age of 74 years. At the age of 18 he began his railway career. He came to Canada at the age of 22 as senior clerk to the chief accountant of the G.T.R. at Montreal. Since that time he has been constantly associated with the company.

Notice has been received of the death in Paris of P. L. T. Heroult, whose prominence as a scientist and whose research work in the commercial production of aluminium and in the development of the electric furnace is so well known. M. Heroult was 58 years old.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21778—May 7—Directing that crossing of Berlin and Northern Ry. by G.T.R. on Wellington St., Berlin, Ont., be protected by half-interlocking plant, derails on G.T.R. 100 ft. from diamond, semaphores on Berlin and Northern 100 ft. from diamond; derails and semaphores be interlocked and operated by conductors of Berlin and Northern Ry.; position of signals be "clear" for G.T.R. and "danger" for Berlin and Northern Ry. G.T.R. bear and pay whole cost of providing, maintaining and operating interlocking plant.

21779—May 7—Directing C.P.R. construct highway crossing at Pine St. Sault Ste. Marie, Ont., cost of constructing and maintaining crossing and changing grades be paid by Railway Company.

21780—May 7—Directing that crossing of G.T.R. by Berlin and Northern Ry. at Bridgeport St., Berlin, be protected by half-interlocker, derails on Berlin and Northern 100 ft. from diamond, semaphores on G.T.R. 300 ft. from diamond; derails and semaphores be interlocked and operated by conductors of Berlin and Northern. Position of signals be "clear" for G.T.R. and "danger" for Berlin and Northern. Berlin and Northern bear and pay whole cost of providing, maintaining and operating half-interlocking plant.

21781—May 7—Reducing joint commodity rates of Chatham, Wallaceburg and Lake Erie Ry. and P.M.RR. in connection with G.T.R. and C.P.R. for carriage of sugar, in carloads, from Wallaceburg, Ont. to Hamilton and Toronto, to 10½c. per 100 lbs. and 11½c. per 100 lbs. respectively, on minimum of 40,000 lbs. per carload; said reduced rates be effective not later than May 25, 1914.

21782—May 6—Authorizing C.P.R. to construct spur for Francis Hankin and Co. and Canada Sand and Concrete Co. from end of existing spur at mileage 7.81, St. Gabrier Subdivision, Lots 175, 176, Les Prairies Range, parish St. Charles Borromee, Que.

21783—May 7—Extending, until July 1st, 1914, time within which G.T.R. submit for approval plan showing location of new station at Summerstown Station, Ont.; work to be completed by November 1st, 1914. And directing that Ry. Co. forthwith remove telegraph poles shown in photographic views No. 1 and No. 3, under File No. 23646; and provide 4-wheel truck to carry milk and cream to movable platform on south side of present platform.

21784—May 8—Amending Order No. 21728, April 29th, 1914, by adding words "over the tracks of the G.T. and C.P.R. Cos." after word "crossing," in 2nd line of operative part of Order, and adding words "and an engineer of the C.P.R. Co." after word "Company" in last line of operative part of Order.

21785—May 8—Authorizing C.P.R. to operate trains over portion of Weyburn-Westerly Branch Line from Woodrow, mileage 145.7 to Shaunavon, mileage 230.8, at speed not exceeding 25 miles an hour, instead of 18 and 10 miles an hour as provided in Order No. 21227.

21786—May 8—Disallowing tariffs and supplements applicable to international traffic filed by G.T.R., M.C.RR., Wabash RR., C.P.R. and P.M.RR.

21787—May 8—Authorizing G.T.R. to operate trains over 25 bridges on its 15th District.

21788—April [illegible]—Directing that C.N.R. construct a road north of its tracks, connecting road allowance between Secs. 5 and 8-18-21, W.P.M., with some street in Elphinstone, Man.; location of new road to be as nearly as may be on line A B on plan dated Winnipeg, 12 November, 1913; work to be completed by June 15th, 1914; 20 per cent. of cost of work herein directed be paid out of "The Ry. Grade Crossing Fund," remainder by Railway Company.

21789—May 1[illegible]—[illegible] with respect to lines of [illegible] C.P. and C.N.R. Cos. or either of them between Mon[illegible] and Ottawa, and between Montreal and Hull, including [illegible] Hawkesbury and Rockland branches [illegible] between Hull and Waltham, Hull and Maniwaki, and Ottawa and Pembroke, all termini inclusive, Order No. 21621, dated April 19th, 1914, by publishing and filing of tariffs by said Cos. under provisions of Subsection 2 of Sec. 328 of Ry. Act, to take effect not later than one week from issuance of this Order, to apply on lumber to Montreal, for export, reinstating rates charged during season 1913 from those stations whence "export" rate has been made same as "domestic" in tariffs suspended by Order No. 21621, which tariffs shall be superseded in so far as they conflict with this Order. Dismissing complaint against increased rates to Montreal for local delivery.

21790—May 11—Authorizing C.P.R. to use and operate bridge No. 133.28, Algoma Subdivision, and bridge No. 102.55, Algoma Subdivision, Lake Superior Division.

21791—May 12—Approving and authorizing clearance between C.P.R. standard coal sheds and rail of side tracks, subject to due performance of Co.'s undertaking to keep employees off sides of cars when operated over said tracks at Co.'s standard coal sheds; and rescinding Order No. 21446, dated March 5th, 1914.

21792—April 30—Amending Order No. 21281, dated February 7th, 1913, by striking out words and figures, "No. 55085-2, dated November 27th," after word "plan" in recital to Order, and substituting therefor words and figures, "No. 55085/3, dated Montreal, December 17th."

21793—May 13—Authorizing C.N.R. to construct across and divert two (2) highways, namely,—between Secs. 20 and 29-28-26, W. 2 M., and between Secs. 29 and 30-38-26, W. 2 M., near Dana, Saskatchewan.

21794—May 13—Authorizing C.N.O.R. to divert Symes Road, Lot 37, Con. 3, F. B., Tp. York, Co. York, Ont., and carry said road under railway by means of subway; clear head room of subway between 14 ft., and clear width 20 ft.; grade on north approach be changed to 5 per cent.

21795—May 12—Approving location C.P.R. station at Larchwood, Lot 11, Con. 3, Tp. Balfour, Dist. Sudbury, Ont., mileage 96.25 on Cartier Subdivision, Lake Superior Division, station to be in accordance with Co.'s Standard Structural Plan 5.

21796—May 13—Authorizing C.P.R. to construct road diversion in Sec. 1-15-14, W. 3 M., Sask.; and construct Swift Current South-easterly Branch Line across said diversion, mileage 4.78, Authority herein granted is without prejudice to right of Board of Highway Commissioners for Saskatchewan to apply to Board of Railway Commissioners, for Canada, at any future time, for separation of grades at said crossing.

21797—May 13—Authorizing C.P.R. to construct, at grade, tracks of through siding across Inches Ave and La Croix St., city of Chatham, Ont., at mileage 64.86, Windsor Subdivision.

21798—May 13—Authorizing C.P.R. to re-construct bridge No. 103.25 on Hamilton and Goderich Sub. Div., near Auburn Station, Ont.

21799—May 14—Extending, until Aug. 15th, 1914, time within which C.P.R. be required to construct and complete subway at Dundas St., city of Woodstock, Ontario.

21800—May 14—approving revised location of C.P.R. main line as constructed, and construction of additional track (double track) on said revision, from point in Lot 6, Rge. 7, Tp. Pic, Dist. Thunder Bay, Ont., mileage 51.49, Schreiber Sub. Div., Lake Superior Div., to point in Lot 11, Rge. 6, Tp. of Pic, Ont., mileage 54.37.

21801—May 14—Approving revised location C.P.R. as constructed, and of additional track (double track) on said revision from point in Tp. 86, Dist. Thunder Bay, Ont., mileage 10.00, Nipigon Sub. Div., Lake Superior Div., to point in Mining Location 85 Z, Tp. 86, Dist. Thunder Bay, at mileage [illegible], Nipigon Subdivision.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

IMPORTANT PRINCIPLES OF BRIDGE DESIGN

SYNOPSIS OF PAPER BY CHARLES EVAN FOWLER, M.CAN.SOC.C.E., M.AM.SOC.C.E., BEFORE PACIFIC NORTHWEST SOCIETY OF ENGINEERS.

The designing of a bridge structure is not merely a matter of figuring the stresses, fixing the sizes of materials, and making a set of drawings. This may all be completed and a design result, but not the design suitable to the location, not such as it should be architecturally, nor for the traffic the structure will carry.

The true design to adopt must come very largely as an inspiration to the designer, who must have the necessary talent or imagination to conceive a bridge that will be the most appropriate and harmonious for a given location and for the existing or future surroundings.

The tower bridge in London, considered by many writers to be a monstrosity, was conceived by the engineer, Sir John Wolf-Barry, to harmonize with the surroundings, and particularly with the old Tower of London in the immediate vicinity. When considered in this light, it is an appropriate and harmonious design; the medieval towers are monumental and the steel work graceful.

The great suspension bridges of New York City are of the same class and are mostly in harmony with the towering buildings in the adjacent territory. The details, however, are not always carried out in the proper spirit, the towers of the Roebling bridge having never been completed and are thus lacking as truly monumental or architectural features; the towers of the nearby Manhattan bridge are too light to harmonize with those of the Roebling bridge or the nearby buildings, although considered alone it is a complete and pleasing design; the Williamsburg bridge is entirely lacking in architectural features, is out of harmony with the present or probable future surroundings, and is only notable in design by reason of its magnitude and the graceful sweep of its cables.

The great arch at Hell Gate, over East River in New York City, is with its 1,000-ft. span and carefully designed abutment towers a truly monumental structure, and the abutment towers are well designed and appropriate; the great arch demanding this mass for backing to properly satisfy the impression of a great thrust properly cared for or resisted.

The Washington bridge across the Harlem, one of the great bridges of the world, is wonderful in its architectural detail, but lacking in the great essentials for a work of architecture. The main structure consists of two spans instead of three, thus giving a pier in the middle; and the approaches are not balanced, thus causing the structure to lack in symmetry. Some of the other designs for this structure, while more simple in detail, would have made a much better structure and a more pleasing one, as they possessed the fundamental features that are necessary to any real work of architecture, simplicity, symmetry, harmony, and proportion.

This is well illustrated by the Eads bridge at St. Louis, with its three great arch spans and appropriate approaches, and although the details of the structure are very simple, it is one of the most pleasing and dignified of the world's bridges.

The conception of a design depends upon no rules, but upon the inherent ability of the designer, limited as we shall hereafter see by certain theoretical and practical requirements. There may be conceived a number of designs for a given location of different types, any one of which would be appropriate and beautiful, but the final decision as to which one of these to adopt must be made on the basis of relative cost, the most economical being usually selected. On the other hand, the most economical should not always be selected, but the best design architecturally be adopted, especially where the difference in cost is not very large.

The cost, for example, of a four-span structure for a given crossing might be found to be somewhat less than for a three-span bridge, and yet it would be wise from an architectural standpoint to adopt the three-span design, as the risk of one more foundation in the river would be avoided, with a probable saving in cost, should difficulties be encountered, that would make the three-span structure the cheaper in the end. In other words, the four-span design would have to be very much cheaper than three spans to call for its adoption. The reason for adopting a three-span design in place of a two-span bridge, might, on the other hand, be based entirely on the architectural features, as the cost and risk of the three-span structure might be much the greatest.

There are, then, two considerations that govern in making a decision as to what design to adopt for any location, the architectural features and the economy of construction, which latter may well be discussed in full before considering the architecture of bridges, and entirely aside from the esthetics of the problem.

The reactions or loads on piers for various lengths of spans must first be determined in order that foundations, abutments, and piers may be designed and the costs determined as factors in the cost of complete structures with different numbers of spans. The load on the pier and the weight of the pier having been determined, the size of the base of the pier may be arrived at by using the formula for the allowable pressure on the foundation bed, as given in the writer's treatise on "Sub-Aqueous Foundations," the character of the foundation bed having been determined previously by careful core borings. Several trials may be necessary before the proper size of a pier is de-

termined, and then careful calculations as to the stability of the pier must be made, and should it be found deficient, as is often the case with deep trusses, or where bascule or lift spans are employed, then it must be increased in length of base until the maximum allowable stresses and pressures are not exceeded.

Then by means of the cost of abutments, piers and spans, the relative costs of various designs may be determined; the weight of the spans to be calculated from reliable formulae or from actual stress and section diagrams. The design of the approaches may be a factor in the relative costs, and in such cases must be included in making the comparisons.

The fact that some consulting engineers make out certain designs to be the cheaper, when comparing them with other designs made up on an entirely different basis, both as to the character of the construction and the real factors of safety, should make any one suspicious of the character of the services offered and disbar such engineers from reputable practice.

The type and design of the superstructure is such a large factor in its cost that this must be fully decided upon before beginning any of the above investigations, and then all designs be compared upon a common basis. Where the grade is high above the stream, with plenty of clearance for floods and navigation, deck spans of some type are, of course, the most economical to employ. Where the bridge is high or falsework expensive for other reasons, it may be best and cheapest to use an arch or a cantilever design, and where very long spans are necessary, either the cantilever or suspension bridge must be used. Where the clearance for high water or navigation is limited, through trusses must be used, although it will often be best to use cantilever spans instead of simple trusses. Through arches or half-through arches may often be employed with good results both architecturally and economically.

The economical design of the superstructure of a bridge requires careful consideration as to the style of trussing, the panel length, and the truss depths. Longer panels and deeper trusses are more economical for modern heavy loads, but for plate and riveted lattice girders the depths are usually much less than for regular trusses. The span lengths for cantilever bridges should always be decided by careful mathematical analysis, as well as the lengths of the cantilever arms, suspended spans and depths. The height of towers and the depth of stiffening trusses for suspension bridges must also be carefully analyzed.

The design of movable spans should be carefully considered, not only with regard to first cost, but as to cost of operation and maintenance as well, but do not get the idea that revolving draw spans are out of date, for in many locations they are the cheapest and the best to employ. Then there are locations where bascule spans are the best from every point of view, but where used they should harmonize with the remainder of the structure if there are additional spans, but in any case those forms must be abandoned that have no pretentions to architecture or beauty, and the same thing may be said with regard to other types of movable spans.

The details for ordinary spans have reached a practically permanent basis, so that standards, at least as to type, are usual. Where the structure is of unusual size, like the Blackwell's Island bridge, the Forth bridge, or the Hell Gate arch, each member must be the subject of critical analysis and study.

Lack of such study and analysis was the cause of the failure of the first Quebec bridge, although the writer's one-time assistant, the late A. H. Heller, had fully covered the points in question in his book on "Stresses in Structures." Great suspension bridges, too, are of necessity special problems throughout and must be studied with greater care than any other type.

The floors of railway spans are usually of a standard type, either with steel stringers and ties or else a steel trough floor with ties laid on the ballast; but the types of floor and paving for highway bridges are so numerous that it is often a grave question what to adopt. The cheapest floor that should in any case be used on a good bridge is one having steel joists with spiking strips bolted to them, to which the floor plank is spiked. The very best floor is undoubtedly a reinforced concrete slab, with from 1½ to 2 in. of sheet asphalt surface, although it may be wise to use a creosoted block surface, the thin blocks being set directly in asphalt on the concrete and either filled with sand or grouted.

Having discussed those things which have to do directly with the economy of bridges, with masonry piers and steel superstructures, we may well discuss structures built entirely of stone or concrete, or of reinforced concrete. Such structures must be fully designed and a careful estimate of cost made in order to make any reliable comparisons. The cost of stone bridges is, of course, the greatest of any type that might be considered, and in the case of the Knoxville bridge, where the cost of the arched cantilever was only $250,000, the bid for the stone arch design was about $1,500,000, thus making it out of the question to use stone where low first cost was a necessity. The same is true to a very great degree with concrete arches, but when reinforced concrete arches are considered, they may be designed to cost but slightly more in many instances than steel bridges, and should be carefully considered where a permanent and artistic structure is demanded.

The writer has for many years made a study of the architecture of bridges, and his book of "Engineering Studies" was the first and only attempt that has been made to formulate any rules of architectural bridge design. It will be superfluous perhaps to say that the statement of an eminent engineer, in a recent report on a great bridge, that beauty could not be secured unless economy was sacrificed, does not meet with agreement from the writer.

There are, it is true, no orders of architecture for bridges as for buildings, nor is there any classification of styles for particular ages possible, as in the case of building architecture, but basic rules must be observed, whether the design be for a building or for a bridge.

Simplicity, harmony, symmetry, and proportion must be regarded in any design that would have any pretentions to beauty or to architectural effect. They are the fundamentals of true architecture, no matter what the structure may be to which thought is to be applied in its design.

Simplicity means first a truth-telling structure, no subterfuges about the lines of stress, no covering up of a concrete structure with a stone facing, no frivolous or inappropriate details, but a strict adherence to the necessary features, whether they are to carry the loads or to ornament the bridge.

Harmony is essential to a pleasing design, for without it the structure would be distasteful. Harmony not only as between substructure and superstructure, between the various spans, between the spans and the ap-

proaches, between the utilitarian features and the ornamental details, but with the surroundings.

Symmetry may or may not be essential to a pleasing design, although it usually is necessary if a truly architectural structure is to result. Where the bridge has a great length, unsymmetrical features are not so noticeable as in a shorter one which may be all taken in at a glance. As is often true in a landscape, balance may frequently be secured by including an unsymmetrical feature. That is, where in one portion of a structure such as a draw or other unbalanced feature must be included that will destroy the symmetry, something must be introduced in the other portion to restore the balance, although symmetry does not result.

Proportion is necessary that the three preceding principles may be realized, and usually when the economical proportions have been determined, they are pleasing. However, in many cases modifications must be made to reach the point where economy and beauty can both be satisfied. Proportion of details employed for ornamentation is quite another thing, and to be harmonious they must have the proper balance.

Examples may be seen in every structure of the proper application of some of these principles, but more often we find one or the other flagrantly violated, so that the remark of S. Shaler Smith to one of his assistants, should be well remembered by him who would reach high rank in his profession—"most bridges are examples of what not to do." Seldom, if ever, do we find a structure that complies with all of the fundamentals, although many bridges approach so nearly to the ideal that careful consideration and analysis are necessary to determine just where improvement could be effected.

Simplicity is best illustrated in its pleasantest features by suspension bridges and arches with no decorations or embellishments of any kind. Harmony is best exhibited where no part of the structure seems to be extraneous and where the structure seems part of the surroundings. Symmetry in its simplest form is where one-half of the structure is exactly like the other. Proportion is most nearly reached when the structure is most pleasing and the truth expressed most accurately.

The basis for a real architectural system for bridges must come, of course, from building architecture and on studying the columned or arched facades of buildings we find an uneven number of openings or arches are employed in the great majority of the world's notable and best pieces of architecture. Where there is an entrance it is nearly always in the centre, with one or more arches symmetrically disposed on either side.

Careful study and analysis of the examples of Egyptian, Roman, and medieval buildings discloses the fact that such an arrangement is most pleasing to the senses and where it has been violated the design is unpleasant. This, then, we may take as the starting point of any design, an opening instead of a pier at the centre, with the remainder of the structure arranged symmetrically on either side. Carried to its logical conclusion, where there is an approach it should have an uneven number of openings, and where there are spandrel arches employed in an arch bridge, they should be of an uneven number.

The Knoxville arched cantilever, designed by the writer, was of five main spans and two anchor arms, thus giving an opening at the centre and a perfectly symmetrical structure, except that one abutment was longer than the other, but not apparent to the eye in a structure a third of a mile long. Economy was violated in the depth of the anchor spans in order to make the bridge harmonious, and the basic rules were all as nearly adhered to as is often the case.

The Market Street arch at Youngstown, Ohio, designed by the writer, was a very difficult problem to solve on account of the side spans having to clear the railway tracks, and on account of the 4% grade of the roadway. The design, however, is symmetrical with the exception of the grade and the approaches, and was made quite harmonious by carrying the sub-trussing of the side spans through at the same elevation as the lattice truss over the arch.

The Mill Creek Park arch, while a short span, shows the possibility of designing artistic bridges for ordinary locations.

Comparing the Memphis bridge by Morison with the Thebes bridge by Modjeski, we can readily see how much is gained in architectural appearance by the symmetrical arrangement of the spans in the Thebes bridge. Comparing the approaches of the Thebes bridge with the approaches of the Forth bridge, we see how much more in harmony with the main structure are the approaches of the Forth bridge than those of the Thebes bridge, although considered alone the latter are of the best design architecturally.

The Grosvenor Dee bridge, at Derby, England, with its 200-ft. masonry span, is one of the greatest bridges of the world, but the paneling of the abutments and spandrels, and indeed all the decorations, are so out of harmony with the great span, that they dwarf it and ruin the design. Compare this with similar details of the Eden Park, Cincinnati, reinforced concrete arch and we find such ornamentation entirely appropriate and harmonious for the smaller span.

European bridges are more often well designed architecturally than those of other countries and the great bridge over the Rhine at Bonn, Germany, is an example where simplicity, harmony, symmetry and proportion are all as fully met and satisfied as has ever been the case in any bridge structure.

The Camelback bridge in the Imperial Palace grounds at Peking, China, is also one of the most perfect of the world's bridges from the architectural point of view and satisfies the cardinal requirements of design.

The best design in the United States is the Connecticut Avenue bridge in Washington, D.C., with its five great concrete arches, and very little fault can be found with the design, except the inappropriate decoration of the wing walls of the abutments. The designing of harmonious and appropriate details in the proper proportion is a study in itself and entirely beyond the scope of this paper. Should designers, however, carefully observe the cardinal principles herein laid down much more pleasing structures would result and a great stride forward be made in bridge engineering and architecture.

The necessity for good construction, especially of foundations, is obvious.

The total output of petroleum in the world for 1913 has been compiled from reliable estimates for foreign countries and from preliminary figures of the United States Geological Survey for the United States, and is given as about 378,000,000 barrels of 42-gallon capacity, as compared with 351,178,[illegible] barrels in [illegible]. In [illegible] the world's [illegible] 777,228 barrels, so that within a 7-year period, there has been an increase of over 80 per cent. The United States has furnished the greater part of the increase, and is at present providing almost two-thirds of the world's annual output. The [illegible] production of the United States [illegible] about 65 per cent [illegible] the world's [illegible].

REMARKS ON THE THEORY OF THE PITOT TUBE

DESPITE the great number of valuable papers and results of tests published during the past few years on the subject of the Pitot tube, hydraulic engineers have not as yet come to any definite agreement as to whether $h = \frac{v^2}{2g}$ or $h = \frac{v^2}{g}$ is the correct formula underlying its action. The following extracts from a paper read by N. W. Akimoff at the recent convention of the American Waterworks Association in Philadelphia, may be of assistance in clearing up a number of points serving as a foundation for argument. Mr. Akimoff is inclined to believe that the contention inherent in the controversies as to whether $\frac{v^2}{g}$ or $\frac{v^2}{2g}$ is correct, is mostly based upon the fact that entirely different premises are at the bottom of such discussions.

The formula $h = \frac{v^2}{g}$ is the same as $v = 0.7\sqrt{2gh}$ and it is not very difficult to build rods that will yield this result or even slightly less, instead of $v = c\sqrt{2gh}$, where c varies from 0.84 down to 0.75, as is the case in some of the rods now on the market.

It is often "assumed" that c really ought to be unity and, therefore, that smaller values of c are caused by the "suction," due to the "trailing orifice," bent back (Fig. 5, c) in the direction of the flow. It so happens, however, that out of all means available for decreasing the value of c, the "trailing orifice" seems to be the least effective; experiments made both in this country and abroad show that the lowest c that can be secured with the trailing orifice is 0.84 and often as high as 0.92, whereas, as said before, other means enable us to bring c down to 0.75 and even to 0.70. Greater "reliability" is claimed by the advocates of the "trailing orifice," however, which point it is not our intention to consider in this paper; our object being to present a few considerations relative to the formula itself of the Pitot tube, and not at all either to endorse or to condemn any particular existing article now on the market.

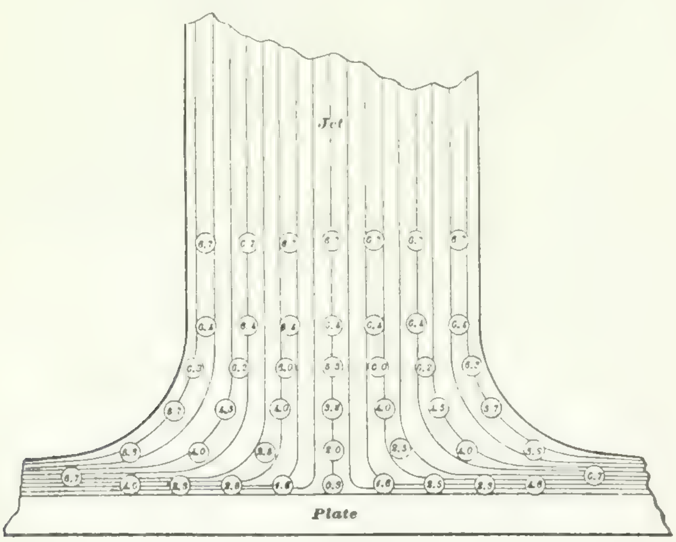

Fig. 1.—Stream Lines and Velocities of a Jet Impinging on a Plate.

We shall first take up the impulse tube itself; the "static" tube will be considered later. The writer will assume that everyone is familiar with the article on "The Pitot Tube; Its Formula," by Mr. W. M. White, published in the Journal of the Association of Engineering Societies, August, 1901. This article, which in our time will perhaps be found somewhat unconvincing, and, possibly a trifle obsolete, contains at least one valuable feature, which will be of advantage in our discussion. In order to substantiate his opinion that in an impact tube, whose impinging surface is one of revolution, the coefficient c, of conversion of velocity head into static head is exactly unity, Mr. White has made many tests, the results of one of which are given in a chart (Fig. 1), taken from his paper.

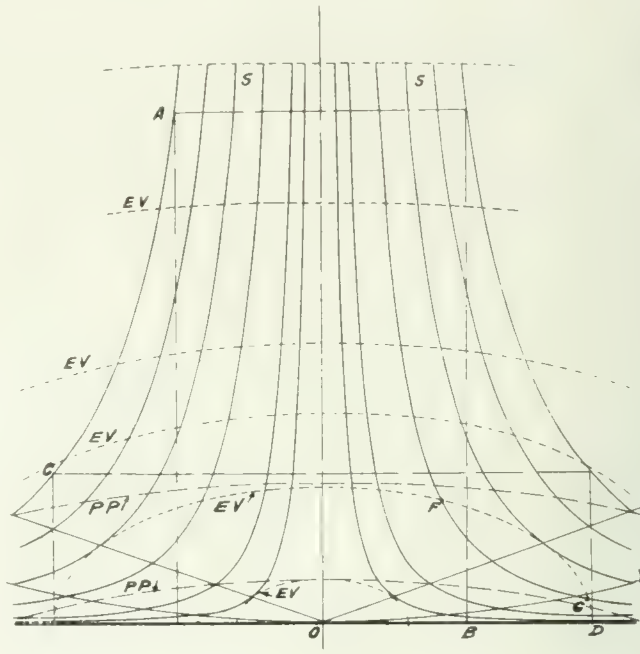

Fig. 2.

A stream of water was directed against a round plate; individual velocities of separate filaments were measured and the results, in feet per second, are marked on the chart.

At the present time it would not be necessary to take all this trouble, the effects of the stream, directed both against a long, narrow strip (dam) and against a round plate, have been carefully analyzed with the following most interesting results (Fig. 2, for round plate only).

1. The stream lines S are curves of third degree, possessing this most curious property: that all cylinders, inscribed in the surface generated by each stream line are equal, so that, for instance, the volume of A-B is the same as that of C-D. The stream lines began to diverge at a considerable distance from the plate. Of course, the size of the plate proper does not in the least affect the general shape of the curves.

2. The curves of equal velocity EV are ellipses, located as shown and having O as centre. Since, in general, these lines intersect the stream lines at two points, such as F and G, it is clear, that somewhere between F and G there must be a point of minimum velocity, where the corresponding ellipse is tangent to the stream line. The locus of such points of minimum velocity will be a straight line, OH, the angle of which with the base will be about 20°.

3. The curves of equal pressure PP will likewise be ellipses, but their common centre will be located below O and is not shown on our drawing. The curve of maximum pressures, (that is of points on each stream line, where the pressure is greatest for *that* curve) will be a hyperbola YOY, tangent to the plate at O.

Careful attention must be paid to the fact that the straight line OH, of minimum velocities, and the hyperbola YOY (of maximum pressures) do not coincide, so that minimum velocity does not mean greatest pressure, which excessive freedom with Bernoulli's theorem might lead us to think would always be the case. We readily forget that Bernoulli's formula has been established for parallel flow only and that it does not hold good for any other kind of flow; at least not in the shape in which it is given in books on hydraulics.

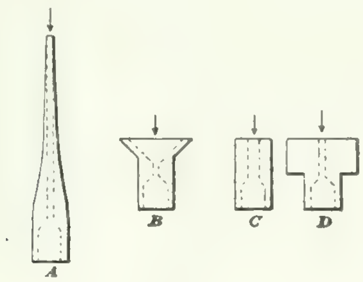

Fig. 3.

Such, then, is the correct aspect of the phenomenon of a jet impinging upon a round plate. A plate, long and narrow, would mean a somewhat different distribution of velocities, etc., and all lines would appear somewhat different from those given in Fig. 2. It follows, therefore, that contrary to the established assumption, the point O cannot possibly be considered the true impact point. Here the "static" pressure is indeed maximum, but the velocity is zero and therefore it is really the ideal point from which to determine the true static pressure, undisturbed by any "suction" or "trailing" effect.

It will, of course, be understood that this static pressure represents the conditions somewhere "up stream" from the plate itself; for instance in Mr. White's experiment, it simply shows the height from which the water falls. In other words, we have here not the "velocity due to a certain head" but the head itself. This may be made to serve as a check, but in itself is not especially instructive or interesting in our present problem. But then, it is perfectly possible and feasible so to calculate almost anything of this sort as to give fairly good results; only, our layout, Fig. 2, or, for that matter, the "practical" sketch, Fig. 1, as given by Mr. White, shows that the middle point is merely subjected to the action of dead water. We might as well have a stationary column at that point.

Any other point, in the vicinity of the curve YOY, of maximum pressures, will be more likely to register the effect of impact, due to velocity, in addition to static pressure at this point.

All the foregoing refers, of course, to a stream acted upon by gravity and directed downward on a horizontal plate, in other words to the condition, illustrated in Mr. White's sketch. In a pipe, with water flowing under pressure, the foregoing conclusions may require suitable corrections.

It is, nevertheless, quite obvious that the point which is generally assumed to be the true impact point, apparently placed against the greatest action of the stream, may prove to be at a great disadvantage, so far as the determination of velocity is concerned.

The size of the plate, as has been already stated, does not enter into our deductions; and the nozzles B, C and D (Fig. 3, taken from Mr. White's paper) will naturally cause the same distribution of velocities and the same effect. The nozzle B is in the same class, because our mere desire to "catch" the energy by means of a funnel-shaped orifice does not in the least alter the fact of the central stream being perfectly neutral, while other stream lines may, indeed, assume a somewhat more fanciful shape than that given in Fig. 2.

So far as the nozzle A is concerned (Darcy's shape), it must be remembered that, unless the nozzle itself is reasonably long, the fittings, etc., back of it should not be neglected. It will be easily seen that a large T or L piece immediately back of a very thin nozzle will cause the formation of stream lines similar to the foregoing, with the same inevitable effect, viz., the neutral stream, possessing the greatest static pressure, but inert, dynamically.

That the rod itself, beside the nozzle proper, will exert a certain influence upon the results, has been very clearly demonstrated by Professors Easby and Pardoe, of the University of Pennsylvania. In their experiments a comparatively small pipe was chosen and the rod was of uniform blade-like cross-section. By means of suitable stuffing boxes the rod was made to pass completely through and extend on both sides of the pipe; so that traversing the pipe meant merely shifting the position of the orifice, and not, as in other rods, the immersion of an additional portion of the rod proper. Under these conditions the traverse curve was materially different from the one usually obtained from such small pipe (4-inch). The curve was visibly more symmetrical and thus proved, beyond doubt, the experimenters' point.

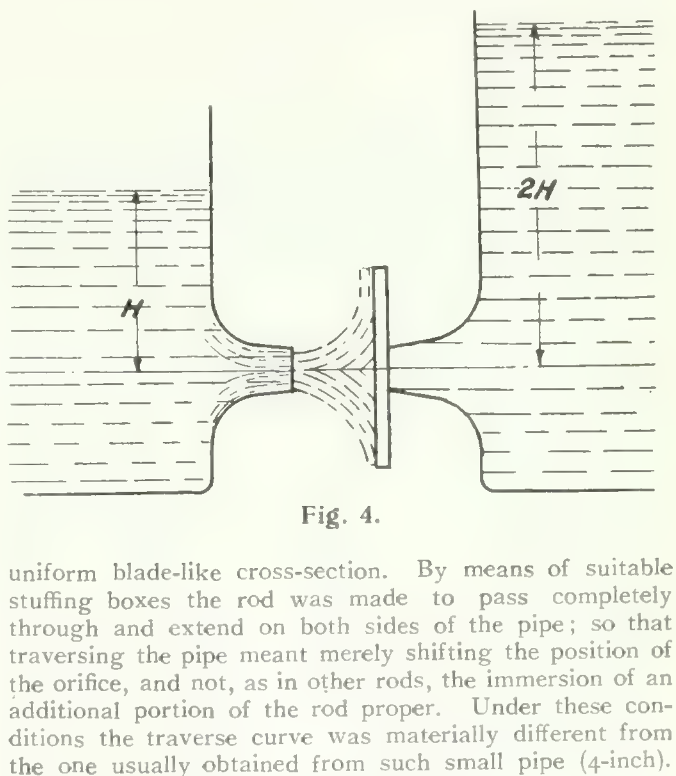

Fig. 4.

The fact has been long established in theory and confirmed by experiments of all kinds, that the *force* (*not* the pressure per square inch) due to an impulse of a jet is $M \times V$, mass times velocity, where the mass is the second-weight divided by 32.2 and the velocity is in feet per second, so that the result is in *pounds*. This immediately leads to $h = \frac{v^2}{g}$, in other words, to the conception of *twice the head generated by the velocity*.

That $M \times V$ is the actual force, due to an impulse, can be clearly proved by an experiment, similar to that described in Professor Merriman's *Hydraulics*, in the

chapter on "Dynamic Pressure of Water," where a jet, acting upon a plate in front of an orifice, is capable of sustaining twice the head, to which the jet itself was due (Fig. 4).

Should the plate be removed the head in both vessels tends to the same value, as was almost exactly demonstrated by Professor Unwin; but does such a condition correspond to our initial problem?

In an experiment of this kind, can we possibly expect any result other than an equilibrium, subject solely to corrections due to frictional and other losses?

Zeuner, if an impartial, conservative authority is to be quoted, in his well-known book on *Practical Hydraulics* (German or French), gives 1.25 as a safe value to be used in $h = \zeta \frac{v^2}{2g}$ while demonstrating that its theoretical value is $\zeta = 2$, he likewise cites a few tests made both by himself, in connection with turbine work, and by others, in experimenting on water scoops, etc., where the value of this coefficient was actually 1.25. Was this because the whole jet was utilized instead of only a small central filament?

Summing up the foregoing, therefore, and without the slightest desire to question the accuracy of the numerous tests, made by well-known experts, the writer does not feel, so far, there is sufficient evidence for the fact that in a single tube $h = \frac{v^2}{2g}$ is the greatest pressure that can be secured; and certain experiments, although made in perfect good faith, rather tend to demonstrate the contrary. So much for the impulse effect.

So far as the suction is concerned, we shall begin by referring to Mr. Ferris' discussion of the same paper by Mr. White. The following are Mr. Ferris' conclusions: (1) The suction effect of the trailing orifice is very little greater than that of the plain static opening, drilled through the pipe wall; and (2) the head, obtained by him was much greater, about 60 per cent., than $\frac{v^2}{2g}$.

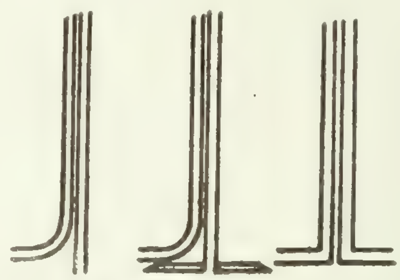
These remarks are very much to the point and we shall now endeavor to generalize them. To begin with, analyzing the suction effect due to the trailing orifice arrangement, one cannot help arriving to the conclusion that, owing to the comparatively low velocities, under which the Pitot tube is operated in practice, there is but little hope to secure any appreciable amount of suction by merely bending back the static tube.

Even in theory it can be proved that there is a certain minimum velocity, beyond which no suction can possibly take place (see Zeuner's book, hereinbefore mentioned).

But there is another point not to be overlooked; the so-called "static" opening, which is sometimes drilled in the pipe or else otherwise finished flush with a horizontal plane, cannot help registering *less* pressure than that corresponding to the "static" head, except, of course, for extremely low velocities. Here water is made to shoot past the opening and it is at this point that some suction effect might reasonably well be expected.

By way of illustration, beside Mr. Ferris' experiment, already mentioned, we might cite a few careful experiments made in Charlottenburg (Fig. 5, taken from Dr. Blasius' article, see *Die Turbine*, January 20, 1910). By k is meant the coefficient in $h = k \frac{v^2}{2g}$. It will be observed from c that the arrangement, which from the standpoint of "trailing" effect should yield the greatest k, actually is much inferior in this connection to the arrangement shown on sketch a, where the static pipe is finished at right angles to the flow.

It is perfectly easy further to intensify the real suction effect. It is well known that, as explained in hydrodynamics, a sudden change in the direction of velocity can cause very abrupt changes of pressure. For instance, in flowing around a sharp corner, even moderate velocities will cause zero pressures or even negative pressures (vacuum, and corresponding interrupted flow). This, then, seems to the writer to be the correct principle on which to work to secure the real suction effect, so that the value of c can be reduced to 0.70 and lower (in $v = c\sqrt{2gh}$).



(*a*) k = 1.82; (*b*) k = 1; (*c*) k = 1.18.

Fig. 5.

This has been experimentally demonstrated by Mr. Paul Lanham, engineer in charge of pitometer division at Washington, D.C., who had a special rod made according to a sketch suggested by the writer. In fact, the coefficient given by this rod seemed to be a trifle less than 0.70, although this rod was not standardized beyond establishing the above point of giving a very low value of c.

CANADA CEMENT COMPANY'S PLANT AT DAUNTLESS, ALTA.

Building operations are about to commence on the proposed $2,500,000 plant of the Canada Cement Company at Dauntless, Alta. There will be five kilns, each 10 feet in diameter, 240 feet high, and will weigh 600 tons. Including the fire brick lining and an average load of material, the weight will be 720 tons. These are the largest cement kilns in use in Canada and will be second largest in the world. A 10-ton gear, is required to drive each kiln and bearings, weighing 15 tons support the weight; while 16 cars are required to transport each together with bearings and gear. Over 3,000 yards of concrete are required for the five foundations. The cost, including installation, will be $75,000 for each kiln. The plant at Dauntless when completed, will have a capacity of 4,000 barrels daily, and will be one of the largest in Canada.

A bill has been submitted to the General Assembly at Uruguay for the construction of a canal to connect La Picada de Almeida, on the River Santa Lucia, in the department of Canelones, with the bay of Montevideo. This new waterway will be named the Zabala Canal. It will be accessible throughout its course by vessels of 200 tons displacement. The cost is estimated at [illegible]80,000.

The Pennsylvania Water and Power Co., has let contracts for the installation of an additional unit of [illegible] h.p. at its Holtwood (Pa.) plant. This will make the eighth unit, and will bring the capacity of the plant up to 111,000 h.p., with provision made for the installation of two more units, when required. Along with this improvement a new transmission line is to be erected between the Holtwood plant and Baltimore, which will take care of the increasing business in the latter city. This work will cost about $400,000.

ENGINEERING AND ACCOUNTING—THEIR RELATION WITH SPECIAL REFERENCE TO PUBLIC UTILITIES.*

By J. B. Scholefield.

AMONG the many changes brought by time none has been more complete than the change in the relations between Finance and Engineering. In times past the successful promotion of any undertaking involving the use or development of physical means was largely dependent upon the possibility of finding an engineer capable of handling the problems to be faced. The financial backing could be much more easily secured.

With the tremendous advance in engineering knowledge, and the heavy drain upon the world's finances caused by the unprecedented developments of recent years, the positions have been reversed. The necessary engineering skill can be more or less easily obtained, but, owing to the ever increasing demand and the multitudinous opportunities afforded, capital is becoming more and more difficult to interest. The requirements of capital are becoming more exacting and must be complied with to the best of our ability.

It is not now sufficient for the man of vision to paint a picture, for him to be overloaded with the necessary funds for its realization. Few projects are absolutely "in the rough" and estimates of the future must generally be verified from experiences of the past. This is particularly the case to-day when so many undertakings involve the replacement or reconstruction of the result of previous efforts. In many cases the profit to be gained is not what might be called an "original" profit but is often in the nature of a commission on increased efficiency or improved methods. The old gives place to the new but the latter pays for the sins of the former and the margin of profit is therefore reduced.

It is in these circumstances that the accountant has come into his own. Starting as the humble scribe to the "creative genius"—the engineer—he has to-day, in some instances, attained a position where the hopes of the engineer rest upon his decision. In all cases greater demands are made upon the accountant and the initiation and continuance of important undertakings depend largely upon the figures he supplies and not so much upon the sanguine expectations of the promoter or the developer.

The foregoing is even more true when we turn from the entrancing realm of exploitation to the mundane sphere of operation. With the increasing population and the disappearance of virgin fields for commercial development, financial attention is increasingly focussed upon existing enterprises and the possibilities for their betterment and economical expansion. Competition, including the competition between different means of production and sources of supply, calls for a closer watch upon the results of operation. Figures supply the medium.

Under these circumstances it should be apparent that it is to the mutual interest of the engineer and the accountant that they should co-operate to the fullest extent and should have a thorough understanding of the difficulties under which they each labor.

When I was asked to address your society it was with considerable misgivings that I consented, for "there is nothing new under the sun" and the setting forth of concrete facts such as an organization like this is interested in appear to me to be probably beyond my ability. However, it occurred to me that some brief remarks on the problems confronting the accountant in which he is dependent upon the co-operation of the engineer might be of value and, at this present stage of the country's political progress, a brief discussion of some points in the valuation of public utilities, in which they are both vitally interested, might be of interest.

In times past there have been unfortunate divergencies between the accountant's final figures of cost and the engineer's original estimates. This was doubtless the fault of the accountant but perhaps may be forgiven as attributable to his inordinate desire for accuracy.

The chief mutual interest of the engineer and the accountant centres round the question of costs. I do not now refer to manufacturing costs, with which we in this part of the country are not greatly concerned, but to the construction costs.

It is essential that the cost of construction be properly kept for the following objects:

(1) The vindication of the engineer.

(2) The scientific provision of depreciation.

(3) The reliable adjustment of cases of renewal and replacement.

(4) The provision of figures on which to base future developments or to recommend new and similar enterprises.

(5) The valuation of property for sale or amalgamation.

(6) The valuation of property for regulation or absorption by the state or federal governments.

The history of most undertakings has been one of small beginnings, and here occurs the first difficulty of the accountant. It is naturally felt, when capital is small and hardly obtainable, that the energy of the organization must be concentrated upon the physical work in progress. The accounting end is given small consideration and the records kept are meager and unreliable. In many cases the engineer is the paramount authority and is able, if he will, to insure the starting of a simple yet complete system which shall be of use in the future and can be elaborated as the enterprise grows. I have experienced instances where it was quite impossible to ascertain from time books or payrolls where the work was actually done and, as expenditure on similar work at several locations was all charged to one account, it was impossible to arrive at the cost of each plant.

The books are often kept at a point remote from the actual work of construction. The bookkeeper is unfamiliar with the nature of the work and the lay of the land and is consequently unable to provide intelligent and appropriate records. A preliminary outline by the engineer, showing the general plan to be pursued and the more important items comprised therein, should be provided.

In large undertakings it is worth while to keep elaborate detailed cost accounts in a separate set of books, the balances of which tie in to the controlling accounts in the general ledger. In smaller projects this is not possible and considerable unnecessary expense and trouble is incurred because the engineer insists on keeping his own records of cost for various parts of the work. This is probably necessary in such instances as require records of cost of excavation, grading, concrete work, etc., so that daily costs may be obtained as a check upon the progress made, but the cost of sections of the work can be adequately shown by the general books if there is a proper understanding between the engineer and the accountant

*Read before the Utah Society of Engineers, January 16th, 1914.

The former sometimes complains that the divisions adopted by the latter are of no service to him. Some preliminary agreement would doubtless have eliminated this excuse.

Unless the work will bear a heavy accounting cost, simplicity of accounting distribution is essential. I suggest that the following divisions will sufficiently cover the majority of cases (excluding large enterprises):

Material and freight.
Labor.
General expense.
Overhead expense.
Financial expense.

The first three divisions would be titles of accounts for each part of the work sufficiently important to call for separate accounts. Overhead expense and financial expense would, of course, be each in one account for the whole project.

The reason for choosing the first distribution is that, in the West, at least, the delivered cost is the important figure. This account should therefore include hauling and handling. By arriving at the unit cost under this head at the completion of the work it will be possible to make comparison in future years when the questions of replacement, renewal, or reconstruction come up.

The common labor cost should be a separate item because rates change so frequently and much of this work is eliminated from time to time by inventions and improvements.

General expense would include all other expenditures directly chargeable to the section of the work. It may be that engineering is so large an item that a separate account would be desirable. This depends upon the individual circumstances. I shall probably be told that my distribution makes no provision for stores accounts. Needless to say, stores accounts are extremely desirable if properly kept. Unless, however, a regular store-keeper is kept and a proper system followed, the result is more unreliable than that obtained by making direct charges to the accounts estimated to incur the expenditure for material and supplies.

Overhead expense should not include Financial expense but should cover only such supervisory and executive expenditure as cannot be directly charged to any one section of the work.

Financial expense, which includes promotion expense, discount on bonds and stocks, interest during construction, incorporation fees, etc., should be kept separately. It is absolutely unjust to charge this as a part of the cost but it is often spread over the property so as to hide the expenditure. The conservative method is, of course, to hold this expenditure apart and charge it off to profits over the life of the indebtedness incurred or as a yearly charge over the estimated life of the assets created by the work.

It will readily be seen that the accountant depends upon the engineer for the proper distribution of expenditure and it is therefore the business of the latter to see that he has the means of supplying reliable information. I need only mention two or three desirable methods in this connection:

(1) Blind check on material received.

(2) Proper issuing requisitions.

(3) Individual daily time slips. The usual time book is a delusion and a snare and leaves the way open for a shirker to neglect the conscientious discharge of his duty.

(4) In case of a more or less elaborate distribution the adoption of letters, numbers, or symbols as a means of reducing the labor of distribution.

(5) Correct records of material returned either to seller or to general stock.

(6) Correct records of material remaining on completion of construction.

Let me point out some errors which are not infrequent and which can be avoided if the necessary information is furnished to the accountant:

(1) Construction originally charged to property account is torn down and replaced by improvement. The cost of tearing down should not be a property charge.

(2) Supplies are charged to property by one company and then sold to an allied company. The sale is credited to earnings.

(3) Property is "junked" and turned into storehouse without record. There is a surplus on inventory which is credited to profits.

(4) Property is torn down and the material used for maintenance without charge.

(5) Overhead and financial expense are omitted from original cost figures when writing off property replaced.

(6) Supplies left over from construction are not turned in to stores or records furnished. They are later sold as operating supplies or used in maintenance without charge.

In the course of the work the main plan will often be modified and the accountant should then be supplied with a simple and timely notification of the change involved.

The distribution of overhead expense cannot be done intelligently without the advice of the engineer. It is entirely wrong to spread this over according to the total cost of the work. In some cases there will be a large labor charge, involving much overhead expense, with little material charge. In another case there may be a low labor charge with the same amount of overhead expense. In another case there may be a comparatively small material charge on work which has occupied much time in contemplation, planning and supervision. In some cases a low labor charge may mean that the class of labor employed required constant supervision and in other cases a high labor charge may mean that much could be left to the intelligence of the men employed.

The engineer should take the completed cost figure and, from his files and his personal knowledge, make a concise report on each division of expenditure so as to indicate the proportion of overhead expense which should be borne by each.

On other points the engineer can and should furnish information. Take, for example, the question of the charge to be made by one project for equipment loaned to another. This charge may be made either by way of interest and depreciation charge upon the value of the equipment when received, or by the difference between its estimated value when received and when returned, plus in each case an agreed profit.

It often happens that the construction and operation overlap and that the construction force is used to a greater or lesser extent in the commencement of operations. In that case operating must be charged with certain time, both ordinary labor and supervision, for supplies used and facilities provided. The information must come from the engineer. This also applies to the proper division of revenue obtained in the transition period.

Certain parts of the work bear, in some instances, what appears to be excessive cost. Only a proper engineering report can interpret the accountant's figures in the light of the difficulties actually encountered so that future valuation and present opinion may be correctly informed.

When actual construction is completed, the engineer can greatly assist the accountant in two ways:

(1) By giving information as to desirable divisions of operating and maintenance expenditure so that the records kept may afford valuable information. He may also be able to suggest proper classification of earnings. This side of accounting is often neglected but is very necessary in comparing periods and in arriving at facts relative to progress and the probability of increase in the future and the justification for additional construction.

(2) The fixing of logical and adequate rates of depreciation. This can be done by a detailed report on the class of construction in each account, its probable life, the estimated maintenance charge and any other useful points. The general practice of using a blanket rate of depreciation to cover a whole plant or even large sections is absurd. The whole question of depreciation calls for a change in treatment. To my mind, the only correct method for a large plant or system is the provision of a depreciation and maintenance fund. After proper consideration by engineers and all concerned the probable yearly depreciation and maintenance cost on the several sections should be determined. This cost should be charged up by even amounts monthly and credited to the depreciation and maintenance fund. Against this fund should be charged the actual expenditure for maintenance, replacements, and renewals and complete reconstruction if the property is rebuilt (if the original construction is exactly replaced). The division of the actual expenditure can, if desired, be kept in subsidiary books.

The advantages of this plan are that comparative accuracy is insured in the rate of depreciation and that the cost of maintenance is equitably distributed so that the earlier years, in which the plant is new, and the expenditure on maintenance is small, bear their fair share. It may be objected that the business is built up in the earlier years for the benefit of the later years. This has been the excuse for manipulations which are responsible for many of the evils we suffer from to-day. In any event, if this contention be allowed, the honest method would be to make allowance for the "building up" process by crediting earnings with an estimated amount and carrying a corresponding charge as deferred for distribution over later years.

Where assets are replaced by improved or enlarged units or parts it is naturally claimed that the increased value should not be charged against earnings. It is necessary, therefore, to charge the cost of original plant cost to earnings and the improved value to capital. The accountant must obtain his data from the engineer as the one familiar with the actual physical change. It is hardly necessary to say that the present day cost of the lost asset should be charged to earnings, not the original cost.

The operating statements issued under this system show a uniformity which is extremely useful as a basis for further capitalization or the marketing of present securities.

A periodical reconsideration of the depreciation and maintenance funds and charges thereto must be had in order to correct the results of any exceptional occurrences or conditions.

The rates fixed should take into account the residual value of the property in reduction of the annual charge.

Depreciation should not be provided on such expenditure as does not require replacement. Therefore, real estate, perpetual right-of-way, excavation and grading, and like items should not be included as depreciable.

The income tax law allows "reasonable depreciation." At first the deductions made under this head will doubtless escape minute scrutiny, but as the Act works more smoothly the authorities will certainly turn their attention to this feature. We shall depend upon the engineers to substantiate our contentions as to rates and conditions. It would probably be of great benefit if this society were to take up the question of depreciation in this section of the country, having special regard to the effects of atmosphere, water, and soil conditions and set forth a schedule of depreciation on well-known standard apparatus and material so that these figures could be used to combat the generally erroneous conclusions of government officials. A result of government rate fixing can be seen in the maximum rate of "5 per cent. of the annual gross outfit" allowed to mines under the income tax law. In the case of one mine with which I am familiar, a mine which is a big producer, it would require 42 years to wipe out the investment if the allowance were based on last year's production, or 30 years if the market value of the stock is considered.

The Supreme Court decided that mining companies could not deduct, for depletion of assets, the difference between the value of ore sold and the cost of extraction. This leaves us without any measure of depreciation, if, indeed, any is permitted to mining companies on other than constructed assets—another instance of governmental accounting. The income tax law corrects this but the decision may serve as an instance of what we may expect from cases brought before the courts.

When we turn to the special instance of public utilities we find that the relation of the engineer and the accountant is particularly important. These undertakings depend for their financial life upon the contributions of a class daily becoming more sensitive—the investor. No longer can the word of one financial power call forth unlimited means for any project receiving his benediction. Facts and figures, verified to the utmost possibility, are demanded and given.

In large projects the continual progress must be shown so that an idea may be gained of the eventual outcome. Additional capital can only be obtained after thorough investigation and, in the capital-limited future, the most favored treatment will be received by the corporation able to show actual and provable figures so arranged as to form useful guides to the twice shy investor.

There is another phase of the future which is of even more importance. I believe that most of us will agree as to the practical certainty of one of two things in the near future: (1) State or government ownership; (2) absolute regulation as to rates or capitalization or both. In either instance some valuation must be made and it will not be the same in both cases. Presumably the government would decline to pay for money not actually invested, whereas if rate regulation only were desired, some provision would be made for the risks attendant upon continued ownership. It may be claimed that court decisions concede the value of some intangible costs, but it would appear reasonable to assume that, in the event of a federal scheme for ownership of interstate utilities, some means would be adopted of overcoming the restrictions imposed by past decisions—some of them contrary to a reasonable conception of public rights.

If the valuation be for purposes of rate fixing it is certain that the value must include all money actually expended, together with the cost of obtaining same and a reasonable compensation for unproductive years. This may include some excessive items but the community

must assume some responsibility for its errors of the past or for the provision of facilities before the locality was ripe for them. The question of depreciation cannot concern the rate-fixing body as a factor in the price to be calculated but only as a factor increasing the rate to be allowed. The depreciation should be allowed on the new value of the plant and cannot be claimed at a figure sufficient to make good the ravages of time in a plant where repairs and renewals have been neglected. On the other hand, appreciation of value cannot be claimed for this is the result of the gift or increase of the very public for whom relief is claimed. In the same way a franchise can have no value other than the actual legitimate cost of obtaining same.

Valuation of public utilities for absolute purchase may be affected by a government right to install competitive plants in case of alleged exorbitant demands on the part of the public utility companies. Assuming that both sides are reasonable in spirit, we may fairly claim that the corporation is entitled to payment for cash actually expended, a reasonable financial cost, the average market valuation for some period prior to proposals of government ownership for the stock issued purely as bonus, a reasonable compensation for the market building period (such compensation to become less as the company grows older) and some value for appreciation where the far sightedness of the promoters can be shown. Depreciation not made good would undoubtedly be deduced and regard would be had to the conditions of ownership and operation as they had affected profits.

The ethics of government acquisition may be said to rest upon the assumption that value conferred by the people may be taken by the people, after allowing reasonable compensation for private capital employed and risks undertaken. Assuming the accuracy of this assumption it is evident that little value will be attached to franchise rights, appreciation through increase of population or age of property, promoters' bonus (except where represented by stock which has acquired a market value in the hands of "innocent" holders), and similar terms. It is therefore essential to show all the legitimate expenditure involved and that records should be easily verified and explained. Corporations able to supply information readily and clearly are likely to receive better treatment than those which must resort to estimates and put forward claims not represented by actual figures.

The presumption stated above excludes all question of replacement value. This method of valuation must be resorted to when original records are not available but is fraught with dangers. If credit is taken for the increased prices of the later date it would be perfectly reasonable to insist that the heavy promotion and financial bonuses imposed in the past, but no longer tolerated by public opinion, be eliminated. If, however, by replacement value we mean the cost to replace the original construction at the original figures, the value of correct records is again evident. There are, however, some values which, under ordinary bookkeeping methods, would not be recorded. Such values are those for right-of-way and land donated and taxes remitted. These have a legitimate value to the company and should be recorded by the man on the spot, the engineer, through his report or by notification to the accountant who can record same by a ledger account note or in some other appropriate book. On the other hand, there are certain recorded expenditures which are not represented by assets to which the corporation has title. These include such expenditures as are made on city streets and in other public places in consideration of rights or privileges acquired. A physical valuation of the property might overlook this cost unless specially segregated on the books or specifically reported.

In conclusion, let me express the hope that this somewhat random paper will stimulate interest in the accounting work of enterprises with which you may be connected. Interest is prone to wane when construction is completed and the humdrum work of operating begins. You can, however, usefully give some attention to the operating records. By suggestions or instructions as to proper division of earnings, by information as to which parts of the property or types of the construction are deserving of special record as to operating costs and results you can ensure useful records. Correct and reliable statements breed confidence, and confidence is the forerunner of enterprise. When enterprise is widespread we all gain, and in the creation of confidence one project successfully constructed and operated is worth a hundred glowing prospectuses.

This paper does not exhaust the subject and is written more as a basis for discussion than as containing only incontrovertible facts. I shall therefore be glad to endeavor to answer any questions which you may care to ask.

SMALL STONE FOR ROADS.

It is a usual custom to specify that no stone in a broken stone road shall be over 2½ inches in diameter, because it is claimed that if larger it will work to the surface. If a mass of loose stone of various sizes is passed over by wheels there is no doubt the larger stones will tilt up when the weight comes upon one end of them and the smaller stones will roll down into the place made vacant; but it does not follow that in a broken stone road rolled with a steam roller and bound together with the addition of fines, that a stone will work to the surface if it is 2 inches below the surface to begin with. In fact the mass is so perfectly bound together that it is impossible for tilting to take place, therefore larger stones than 2½ inches can be used in road construction, especially for the lower course.—Canadian Municipal Journal.

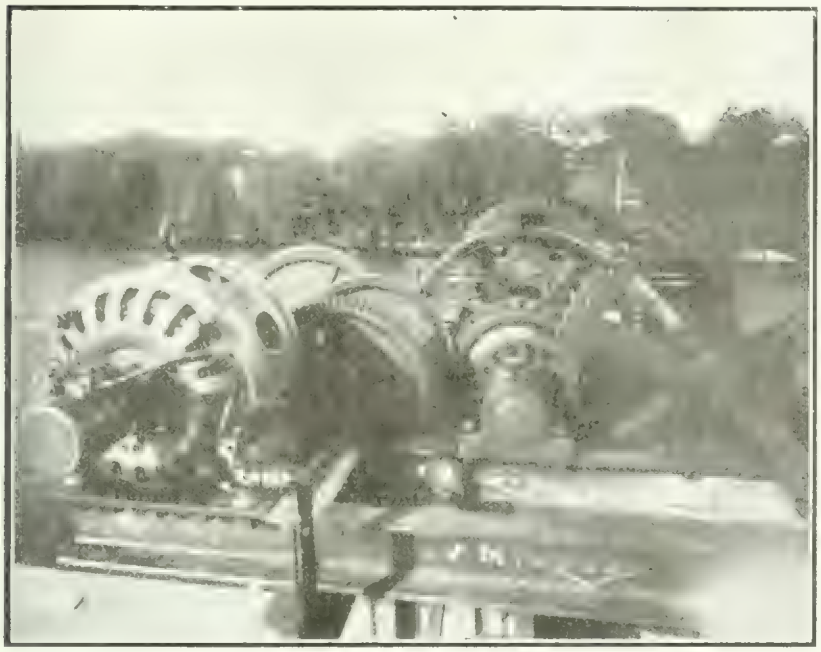
A steel car of special design is being adopted by the C.P.R. The roof of the car has been made in the form of a compromise between the clerestory and the turtle back types, and seeks to retain as far as possible the advantages of both, offering the maximum of light and ventilation. The car is 10 feet in width and 82 feet in length and seats 84 persons.

A compromise bill to regulate the water power diversion rights at Niagara Falls has been agreed upon at a conference held on May 13 between the Secretary of War and representatives for the United States of the House of Foreign Affairs Committee. The bill gives the Secretary of War the right to issue revocable permits for a daily diversion averaging 15,600 cubic feet per second on the American side, and the importation of 250,000 h.p. from the Canadian side. The control over the rates, tolls and service is to be left to the state of New York.

A contract has been recently made between the Italian State Railways and the Società Italiana Westinghouse, of Vado, Liguria, for the electrification of the 27-mile railway between Genoa and Savona; and the electrification of the 30-mile railway between Savona and Ceva, has already commenced. Work of electrification of the Genoa-Savona line is to be completed within 3 years, this line forming part of the railway between Genoa and Marseille, France. By June 1st the railway between Savona and Ceva will have been electrified as far as San Giuseppe (11 miles), one of the principal thoroughfares for the coal-carrying trade of northern Italy. Electricity will be utilized for the freight as well as the passenger services of these lines, and the electric locomotives to be used will be the same as those now in use on the Italian railways from Genoa through the Apennines and the Giovo, which were made by the Società Italiana Westinghouse.

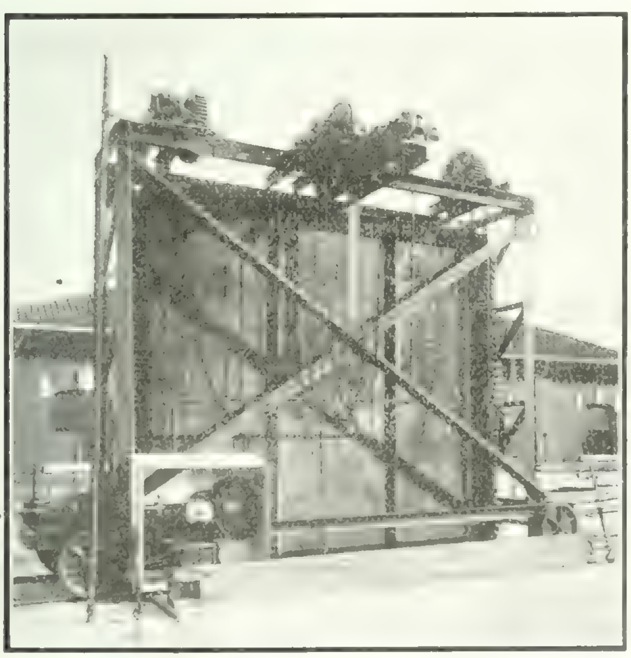
NOTABLE SLUICE GATE ON OTONABEE RIVER.

THE Auburn Power Company development on the Otonabee River possesses a number of interesting features, among which might be mentioned the specially designed travelling sluice gate by means of which the water can be shut off from any of the five wheel pits. The accompanying illustrations show this sluice gate and the gearing whereby it is operated.



Operating Mechanism of Travelling Sluice Gate.

The Auburn Power Company, which was purchased about four years ago by the Electric Power Company, operated a plant for a number of years consisting of one 250-kw., 2,300-volt, three-phase, 60-cycle generator and exciter; one 100-kw. and one 40-kw. unit, both 550-volt, d.c., compound-wound railway generators. These were driven by water wheel and supplied light and power to Peterborough and power to the Peterborough Radial Railway Company. Upon purchasing the plant, the Electric Power Company planned a larger development, the construction of which took place in 1911.



Sluice Gate in Raised Position.

The main dam is situated about 1,200 ft. north of the power house and is constructed of concrete with piers 6 ft. thick and stop-log sluices 20 ft. wide. Its maximum height is 24 ft. and its length 452 ft., including the intake to the head canal, which occupies a total width of practically 100 ft. Each sluice has a depth of 10 ft. below normal head water level and provides a total discharging capacity of 26,000 cubic feet per second. The stop-logs of both intake and dam are handled by chain winches.

The head canal, 1,200 ft. long with sides sloping 1½ to 1, and faced with 9 inches of reinforced concrete, varies in width from 74 ft. near the head works to 83 ft. immediately above the power house.

Articles dealing with the design and construction of this interesting plant appeared several years ago in *The Canadian Engineer*, but the above data are given to better describe the sluice gate with which this article deals.

Of the five wheel pits, four were designed for power units and the fifth for the exciter turbine unit. Each wheel has a net entrance area of 224 square feet to shut off the water quickly and completely in cases where repairs or examination of the turbine gates or runners are necessary. The Stoney sluice manufactured by Ransomes and Rapier, Limited, and illustrated herewith, was installed. The dimensions of this gate are 15 ft. 3½ in. wide and 14 ft. 3 in. high. It is constructed of a riveted boiler plate and supported by a travelling gantry of structural steel, as shown. The apparatus is mounted on cast-iron wheels 2 ft. in diameter with a 9-ft. 8-in. base. It operates on rails at standard gauge.

The arrangement whereby the sluice gate can be lifted or lowered even under a full head of water with the turbine gates opened full, consists of a set of circulating rollers on each side to run in the concrete stop-log gains. When the gate is closed leakage is minimized by the settling into place of adjustable side bars.

The gate is fitted for both electrical and hand operation. It may be raised or lowered against quickly running water passing through the opening under the maximum available, in the space of 2¼ minutes by electric motor. If operated by hand, lowering takes 4 minutes and raising 60 minutes.

The mineral production of coal and coke in British Columbia [illegible] No. 1, 1914, of the British Columbia Bureau of Mines as follows:

ENGINEERS' ESTIMATES AS THEY AFFECT THE CONTRACTOR.

THE following article, from a paper read by P. R. Fletcher, to the Illinois Association of Municipal Contractors, of which he is president, has to do with a number of points of interest both to engineers and contractors.

The United States government, the legislatures of all the states, the officers of every city, village and town, annually levy an appropriation to pay the expenses of running their respective governments for the succeeding year. Every railroad company and industrial corporation in like manner makes an estimate and appropriation for their corporate expenses. This must be done in order to keep the cost of operation and maintenance in reason and to limit the entire cost to a fixed sum of money which they anticipate receiving.

In like manner the engineer in preparing his estimate of the cost of any improvement should with care and deliberation go into all details and arrive finally at a sum which will be sufficient to pay the total cost of this improvement and all expenses connected therewith. This estimate should be ample and liberal to allow for all the requirements of construction and the contingencies which might arise.

There is occasionally an estimate for public work in the territory in which I have operated, that I would call reasonable; there are some that are fair, more that are low—and some, very low. Engineers' estimates are invariably low. I have therefore taken for my text the following clause, found in every special assessment proceeding in the state of Illinois: "I hereby certify that, in *my* opinion, the above estimate *does not exceed* the probable cost of said improvement and the lawful expenses attending the same and connected therewith."

In that one word "my" lies the authority for the estimate, the value of the estimate, and whether or not it is adequate for the construction of an improvement. By that one word the state of Illinois has given its authority to an individual to carry out its constructions and to prepare an estimate for vast sums of money. It has not hampered him except as to the word "exceed" and, as everything is left to his personal opinion, the value of that word is negative.

At the first sight of this certificate, one would think that this estimate must be exactly what the proposed work would cost, and could not exceed that sum. That is what it is intended to be, but, with the fluctuations of labor and material, and other causes, estimates vary a great deal, and if not made with due care, by an engineer who has had a great deal of actual experience and who has kept cost accounts on construction work, will often prove insufficient.

The city engineer who does all his work in one city becomes familiar with all the conditions entering into the cost of work in that city, and usually makes conservative and reasonable estimates. On the other hand, if he uses the same schedule of prices of labor and material upon going to some other city or village, the estimate may vary either way, and if too low may cause the non-letting of the contract. Again, there are many instances where the engineer has made fair and liberal estimates, according to his judgment, but has been compelled to lower them on account of the opinions of some members of boards of local improvement, who consider the estimate too high for that particular locality. Low estimates often result in the failure to let the contract and the abandonment of the proceedings, the letting of the contract above the estimate necessitating a supplemental assessment, or the letting of the contract to undesirable contractors.

Less than a decade ago estimates of cost, both by engineer and contractor, were generally mere guesses. Both, however, are beginning to realize the value of keeping construction costs. Both in estimating and in carrying on construction, methods and costs are taken into consideration, so that a better understanding now exists as to the difficulties to be overcome in construction work.

Though every engineer and contractor has a different method of making estimates of costs, in the main and important details they are similar. For example, anyone estimating the cost of concrete per cubic yard can obtain prices from the dealers on the aggregate, sand, cement, steel and lumber. The exact amount of each material needed for a cubic yard can be calculated and set down without any guessing. There are only two items—the cost of mixing and placing and the cost of erecting and removing forms, both items of labor—that remain to be estimated. By consulting some practical concrete man who does this kind of work, or taking it from cost records, the estimator can ascertain the cost of these items. Adding to it allowances for plant and general expenses, the contractor's legitimate profit and discount of paper, he has a fairly accurate estimate. This method reduces guesses to a minimum, and instead of a guess in a lump sum, what little must be done is confined to a few items, generally a small per cent. of the whole. Those who follow this method and do much estimating will soon learn the various man and machine units of work per hour or per day, so that the only uncertain element of labor cost will be the fluctuation of wages.

There are many conditions which affect the fluctuations of wages. Men may be plentiful when a job starts, but wages may increase, due to the beginning of other work in the same locality or generally good business conditions, and labor become difficult to obtain. In many cities, labor unions are in control of the situation and a union scale of prices is in effect and must be met. In many smaller villages and cities, no satisfactory floating supply of labor is to be obtained. The contractor must import laborers and provide a place to sleep and feed them, an added cost on small contracts. Wages paid to local labor are always higher for an outside contractor than the prevailing local scale, usually about a 25 per cent. increase.

Local laws may also affect the labor costs. City ordinances imposing regulations on maximum loads, etc., may increase the cost of the work. The engineer must look fully into the wages paid in any locality where work is to be done and also into the many conditions which might arise.

Look Out for "Contingent Costs."—In the case of materials to be used, there should never be any guess work as to their cost. Before the estimate is compiled, prices of all the materials, based on the approximate amount needed, should be obtained in writing from the manufacturers or dealers. In the request for such prices, it should be stated what the materials are for, and about when and where they will be required.

Every contractor is familiar with the items of contingent cost encountered in nearly every specification. He reads them over and says to himself, "Oh, that isn't much; that doesn't amount to anything." It does not, if there were only one; but, taken in the aggregate and put into dollars and cents, it represents a large item of cost. If he does not figure it, his profit is reduced; and the

probable reason he has never figured it out is that he could not get his bid under the engineer's estimate if he had—for the very reason that the engineer had omitted it also. Here is the big question: "Do engineers ever figure the contingent cost and add it to their estimated cost?" I believe that here is the true reason why many estimates are too low.

The following items of contingent cost enter into nearly every contract:

1. Expense of looking over the proposed work, attending the letting and closing the contract, if successful.
2. Attorney's opinion as to legality of the special assessment proceedings and bond issue.
3. Cost of the surety bond.
4. Cost of maintenance bond.
5. Cost of the liability insurance policy.
6. Moving outfit to and from the work.
7. Plant maintenance.
8. Tools lost, broken and stolen.
9. Wasted material.
10. Demurrage.
11. Losses due to weather conditions and damages of the elements.
12. Pay roll and expense of outfit in rainy weather.
13. Pay roll of superintendent and foreman for three months of the year, when not at work.
14. Local charges for use of water.
15. Broken drain or water pipes.
16. Unforeseen damages to walks and private property.
17. Cost of inspection of materials.
18. Stakes and help for the engineer.
19. Barriers and red lights.
20. Lost, torn or damaged cement bags.
21. Being a good fellow.

I could explain each of these items more fully, but the mere mention of them will suggest many instances to every contractor. Every one of these items enters into the cost of an improvement. Each is as much an item of cost as labor and material. Taken separately, they amount to but a small sum, but in the aggregate they total from 10 to 15 per cent. of the cost of an improvement. How many engineers take cognizance of these items and include them in their estimate? Yet their specifications and contracts call for them.

No business can succeed without profits, and no contracting company can succeed, and stay in business, without them. This leads to the question, "What constitutes a fair net return on municipal work?"

The contractor's profit depends on the price he bids for the contract, and often varies for the same class of work. In early spring he may bid very low, to get his organization ready for the season, especially if he carried no work over from the preceding year. Later on he, perhaps, obtains contracts at legitimate prices, thus averaging up on the year's business.

On force account work, with every facility at hand to do work, the usual allowance for use of tools and profit is 15 per cent. Gillette figures profit on the basis of 10 per cent. on the cost of material and 33½ per cent. on the cost of labor. This would probably average about 20 per cent. on the whole contract.

Contractors for municipal work are paid in cash or bonds. The occasions when they are paid in actual currency are so rare that they need not be discussed. These bonds are of two kinds: the municipal bond, guaranteed by the city or village as a whole; and the special assessment bond, issued by the city or village in anticipation of the collection of the tax upon each lot or parcel of land benefited by the proposed improvement. Here are two classes of bonds issued by the same city or village for the payment of the same class of work, each drawing 5 per cent. interest, each taken by the contractor at par, yet of very different market value.

The special assessment law of the state of Illinois is considered very much superior to the similar laws in Iowa, Wisconsin and Indiana, irrespective of the fact that where only 5 per cent. interest is paid in Illinois 6 per cent. is paid in these other states. The special assessment bonds of these states readily sell for par, owing to the increased rate of return on the investment, and the public buys them for the reason of that particular attraction. The Illinois bonds assessed on relatively the same kinds of property are sold at a discount of from 5 to 10 cents on the dollar, in order to net an average of 6 per cent. or more for the time that they have to run.

Here, then, we see the propertyholders paying nominally 5 per cent. on an inflated cost of an improvement according to the state law, but paying 6 per cent or more on the actual cost. This difference of cost of the work, ordinarily termed discount, must be added to the engineer's estimate as a part of the cost of an improvement. This discount is not always 5 per cent., but varies as the money market changes. When money is plentiful, bonds can be marketed at 95, but during the last year many have sold for less, if they could be sold at all.

Special assessments are levied against every lot or parcel of land benefited by the improvement, according to such benefits, and the assessment must be equitable. The amounts so assessed are spread irrespective of the value of the lot or the owner thereof. If the property assessed is improved, the value is greater and the security behind the bond is increased. If the property is vacant and poor in value, it has a tendency to decrease the security of the bond, unless it is so located that its improvement or the growth of adjoining property enhances its value.

Again, many assessments are spread against property which has been sold for taxes and been forfeited to the state. In this case, the state pays no special assessments. Hence, in looking over proposed improvements before the letting, the contractor usually examines the assessment and if he finds property forfeited to the state, it reduces the amount available for the construction of the improvement by the total amount of the forfeitures. If the estimate, after taking off the forfeitures, is too low to do the work, the contractor either must not bid at all or else must bid above the estimate. From these facts it follows that it should be the duty of the engineer to look over property before making his estimate, to ascertain its condition, and make his estimates accordingly.

Make Sure of Value of Bonds.—The first duty of the contractor, when he receives bonds for work, is to see that they are good. He must depend upon the expert attorney to advise him. But such advice, however favorable, will not force a propertyholder to pay his tax for an improvement, nor will it force the state to pay a tax upon a lot which has been forfeited to the state for non-payment of taxes. No special assessment bond becomes forfeited if every lot or parcel of land pays its tax. If property that is assessed for special assessment improvements is clear as to title and is worth as much or more than the assessment, there is not much doubt of the assessment being paid. It is this doubt or possible chance of a forfeiture that bankers and bond-buyers shy away from. They use it as a club to force the contractor to sell his bonds at their price. After having the opinion of the expert and of

their own legal talent as well, they send representatives to look over the property assessed, and if there is no possible chance of a loss, the contractor may be offered 95 per cent., if 30 per cent. of the property is vacant, 92 per cent. If there is a forfeited lot, he will get no offer at all.

I am going to suggest two remedies that I am positive, if made law, would have a good effect on the market value of these bonds. As they depend upon the engineer's estimate they may properly be included here.

First, the engineer's estimate should be ample; enough so that after paying the contract and the 6 per cent. allowed by law for the expenses of making the assessment, court costs, etc., there would be left a residue. Our present law requires that after the cost of an improvement is determined, the residue shall be rebated to the propertyholders before they pay their assessments. They pay only what is actually required. My suggestion is that no rebate shall be made until the final bond is paid. I contend that if the property owner elects to take five or ten years to pay his debt, he should pay all expenses connected with it. I contend that the contractor should not assume the collection nor stand the responsibility of the non-collection of special assessments. If there were a residue or reserve left in the special assessment fund, over and above the obligation or requirements of that assessment, it would undoubtedly go far as a guarantee toward insuring the full payment of every bond and the interest thereon, in case of a possible default in the payment of some installment.

Secondly, 6 per cent. is allowed by law to reimburse general fund accounts for cash advanced on account of the expenses of levying all assessments, and this 6 per cent. is always drawn from the first installment. Thereafter there is no fund to pay any expenses which may develop on account of the special assessment. If some of the propertyholders pay their assessment in full, the interest stops on their portion but the bonds continue to run until called. Here is a loss of interest and no fund to pay it. There might be a default on some payment of an assessment and no fund to pay it. The bonds are obligations of all the propertyholders, and inasmuch as the state has seen fit to assess them 6 per cent. for the making of an assessment, I can see no valid reason why another assessment of, say, 5 per cent. should not be levied and held as a sinking fund or reserve, to pay the loss of interest and forfeiture, if any, and at the final payment of the last bond to be rebated to the propertyholders.

The assessing and creation of this reserve will, in my opinion, bring the value of special assessment bonds to a higher plane as marketable and investment securities. Contractors who, in bidding heretofore have figured a return of 90 to 95 cents on the dollar, would, if these provisions were a law, be able to figure on the basis of nearly par. If the creation of this reserve acts as I think it will, I cannot see that the propertyholder eventually pays any more than he does at the present time. What he now pays for as discount will be offset by the increased value of the bond.

The present state law requires that interest shall be paid upon all of an assessment except improvements put in upon the one-year plan. There are a great many such improvements, so small in total amount as to dollars and cents that it is impossible to make them in 5 or 10 installments, where each installment must be a multiple of $100. Very often these improvements are put in in the early part of the season or late in the fall, and in either case, the contractor must wait a year or year and a half for his money without interest. I believe the laws should be amended so that this kind of paper would bear interest, putting it in the marketable class of securities.

There seems to be a dark cloud in our special assessment law in regard to interest on the first installment where there are deferred installments. The ordinance usually sets forth that all installments except the first shall draw interest at the rate of 5 per cent., yet all municipalities collect the interest on the first as well as on successive installments.

Some municipalities issue vouchers on the first installment which bear no interest, but more of them issue those bearing interest. The former apparently have the law with them; the latter do it because they think it fair and honest, believing that as long as they collect the interest on the installment they should in turn pay it out on the voucher or bond. The special assessment law should be so amended that all installments shall bear interest and that all vouchers issued against the first or succeeding installments shall draw interest.

Summing up, an engineer's estimate, to be fair, conservative and reasonable, must be based on the following:

1. The actual cost of material and labor.

2. Contingent costs, amounting to from 10 to 15 per cent. of the above.

3. Contractor's profit, amounting to from 10 to 30 per cent. of the first two items. This will vary according to whether the contract is hazardous and difficult, requiring a large amount of special equipment, or whether it is comparatively easy, requiring but little equipment.

4. Allowance for converting the bonds into cash, amounting to at least 10 per cent. of the total amount of the contract.

C.P.R. TO USE FUEL OIL IN BRITISH COLUMBIA.

The chief engineer of the C.P.R. has investigated the cost and feasibility of using oil in the locomotives on the Cascade subdivision of the British Columbia division of the road with the result that, both in passenger and yard engines, oil tanks will be established at Vancouver, Coquitlam, Mission Junction and North Bend to supply the fuel for the locomotives. Oil has been used for fuel purposes for some time on the sections between Kamloops and Field, and also on some of the branch lines of the province. After the engines on the Cascade division have been changed and placed in commission it is intended to extend the plan to the section between North Bend and Kamloops, completing the change on the entire British Columbia division.

Fuel oil consists essentially of carbon and hydrogen, and the proportion of the latter is high enough to add materially to its heating power. It contains little or no oxygen to reduce the heat units obtainable from it, and it gives out much more heat, weight for weight, during its combustion than coal. Fuel oil also owes part of its superiority over coal in heating power to its greater freedom from moisture, ash and other agents. It is sufficiently accurate to regard the reducing effect of mineral matter, moisture, etc., on the heating power of coal as due to displacement of combustible matter. A coal containing 5 per cent. of ash and 5 per cent. of moisture would, so far as these constituents are concerned, contain only 9 lbs. of combustible matter in each 10 lbs. of coal. The ash and mineral matter in coals vary greatly. The moisture may rise to 10 per cent. and over, and ashes of 40 per cent. and over have been recorded. Fortunately these are excessive figures, and the proportions often run below 5 per cent. When the ash and moisture are low (and in some coals they may be as low as between 2 and 3 per cent.) the higher values for the heating power are possible. Fuel oil, however, is readily obtained free in a high degree from these constituents. The United States Government refuses consignments containing more than 2 per cent. of moisture, and insists on its being practically free from mineral matter. The higher proportions of carbon and hydrogen in fuel oil, and the practical absence of substances exerting a depressing effect on the heating power, explain the greater number of heat units obtained during the combustion of oil.

COST KEEPING IN COUNTY ROAD WORK.

In a paper read by Mr. R. P. Boyd, assistant state highway engineer of Alabama, at the annual meeting in January of the Alabama Association of Highway Engineers, the importance of cost keeping in all road work done by counties was emphasized, and the benefit that might be derived from an accurate system of cost keeping brought out. The following argument is presented:—

It is the engineer's duty to keep the cost of all work done by the county, and it should be one of his first duties to find out what work the county is doing is costing and to reduce that cost by engineering skill, good judgment and common sense.

A few engineers, some foremen and nearly all county commissioners object to cost keeping and the expense incurred.

It is unnecessary to argue here that an engineer on road work is necessary. But does the expense of cost keeping pay a county? Why does every business house go to the expense of keeping cost sheets and accounts and employ bookkeepers and auditors? Because it is absolutely necessary that that business know what each item of expense is and try to reduce the expense to a minimum. Why do the railroads keep the cost per ton-mile of each class of freight hauled? Why does the United States Government keep the cost per cubic yard of all classes of work done on the Panama Canal? Because these corporations and the government realize that they must know these small items of expense, which, if overlooked, soon amount to big sums. If this is true in business, why is it not true in county road work? Isn't that a form of business and shouldn't it be handled in a business way?

One of the first questions asked the Highway Department on going to a county, is: What will a road cost, or what will the grading cost? That same county has been doing road work since the county was established and does not know what its work is costing per cubic yard or per mile. Would you handle your own business in such a manner? How can you handle your road work in a businesslike way? Employ a competent engineer and demand that he show you results. If he can reduce the cost of your work to more than pay his salary the county has a good proposition and knows what it is doing.

For argument's sake, say that you have one outfit of ten teams working on the roads. Under ordinary conditions that outfit should move in grading from 200 to 300 cu. yds. per day, or an average of 250 cu. yds. Suppose that they work 20 days during the month, making 5,000 yds. moved for the month. Suppose that your engineer stakes out the work, cross-sections it and keeps the cost, and he finds it is costing 30 cents per cu. yd.—and we have found that in many counties it is costing that and more. If this is the case, something is wrong with the management of the outfit and the cost should be reduced. Contracts are being let all over the state for grading from 20 cents to 25 cents per cu. yd. Suppose the engineer can reduce the cost to 25 cents per cu. yd. In the one month you have saved on the outfit $250, and if there are more outfits the saving is increased. Can you afford to employ a competent engineer to make this saving?

Again, suppose that the engineer finds that the outfit is moving only 1,000 yds. of earth during the month, and under the conditions it should be moving 2,000. He knows that something is wrong and takes steps to correct it and by careful study finds the trouble and increases the output 1,000 yds. for the month, thereby reducing the cost to half.

The cost keeping is only one of the many duties of the engineer, but it is one that is often neglected in counties that have engineers. It is very easy to keep a system of cost accounts, and unless your engineer is on the job the entire time, the foreman must be required to keep the time.

Of course, on contract work it is necessary to know the cost of each item in order to make a fair settlement with the contractor, and no contract work should be undertaken without an engineer, for either the country or the contractor will lose by it.

The most complicated cost keeping arises when convicts are being used and it is desired to find the cost of different classes of work. The first thing necessary is to find the cost per day of each convict and each team. Suppose the outfit has only 30 convicts, 3 guards, 10 teams and a foreman. If these 30 convicts work 26 days during the month, then there are 780 convict days during the month. To find the cost per day, divide this 780 convict days into the total cost of all convicts, including supervision, guarding, feeding, clothing, medical attention and every item of cost. Suppose this amounts to $273 for the month, then the cost per day per convict is 35 cents. In the same way we find that the teams have cost, say, $390, or $1.50 per day. Now, if the foreman keeps on his time sheet or book what each man and team is doing and turns it over to the engineer, it is an easy matter to figure the cost of each class of work. For instance, suppose 10 teams and 15 men are working on a fill for three days. The cost of that fill would be:

$$
\begin{aligned}
15 \times .35 \times 3 &= \$15.75 \\
10 \times 1.50 \times 3 &= 45.00 \\
\hline
\text{Total,} \quad & \$60.75
\end{aligned}
$$

If the fill contains 400 cu. yds., then the cost per yard is 15.18 cents. These figures are assumed. Some actual cost data on convicts taken from a state aid road in Bullock County are: Cost of maintenance of convicts per day, 39.2 cents; cost of teams per day, $1.29. At this rate the grading cost 15.2 cents and sand-clay cost 15.3 cents per cu. yd.

Occasionally you find a foreman who rebels at keeping these cost items, but generally that man is afraid to know what his work is costing and he is not honest with himself or the county. In most cases the foreman is glad to find what the cost is, and tries to improve his work and his own efficiency as a foreman.

These figures are not mythical or hearsay, but are tried and proven facts. Think of what your county is doing and try to better road conditions. And the first step is to get an engineer, and the next to keep cost accounts.

A definite announcement has been published to the effect that the Northern Navigation Co., one of the most important corporations operating in Alaskan waters, has sold its steamers, barges and terminal facilities to the American Yukon Navigation Co., and the latter will continue to transact the transportation business to all points on Yukon River and its tributaries. The Northern Navigation Co., which was controlled in San Francisco, operated 43 steamers and 54 barges, and owned terminal facilities in Alaska. The American Yukon Navigation Co. is stated to be backed largely by English capital, and to be a part of a big organization which includes the White Pass and Yukon Route owning and operating the railway from Skagway to Whitehorse and steamers and winter stage lines thence to Dawson.

NEW BRIDGE AT PORT COQUITLAM.

As announced in the Construction News columns of May 14th issue, a new bridge is to be erected by the Department of Public Works of British Columbia over the Pitt River, at Port Coquitlam, about 20 miles east of Vancouver. It will be located about 400 yards above the Pitt River bridge of the Canadian Pacific Railway, the substructure of which was described in *The Canadian Engineer* for June 19th, 1913.

The proposed bridge will have timber trestle approaches 540 ft. and 270 ft. at the west and east ends respectively. The bridge proper will rest upon 9 concrete piers, constructed upon timber cribs, the two outer piers being protected by timber piling. At this point borings have indicated a light clay and mud river bed, for a depth of approximately 150 ft. The maximum depth of water at high tide is about 56 ft. and at low tide 50 ft.

The superstructure is to consist of 7 spans which formed a part of the bridge purchased from the Canadian Pacific Railway Company, this bridge being the one that has just been replaced by the new double track bridge described in the article referred to above. It is a single-track construction and has been in use approximately six years. The entire bridge was purchased intact for the sum of approximately $70,000.

The swing span is designed to give a clear opening of 93 ft. on either side of the pivot pier. It will have a clearance of 24 ft., while the trestle approaches will be 24 ft. in width. The deck of the bridge will be so constructed as to provide for electric railway tracks if necessary at some future time.

The portions of the bridge for which tenders are now being called are the complete substructure, including guide piers and trestle approaches. The contract for the transfer of the Canadian Pacific Railway bridge to its new site was let some little time ago.

The estimate of cost for the construction of the complete bridge is $450,000.

The distance of a sea mile varies in different parts of the globe. At the Equator a knot would be 6,045.95 feet; at the Poles it would be 6,107.76 feet, and in the latitude of the ocean route from Europe to New York about 6,080 feet. Nautical surveyors take into account these small differences, and the measured nautical mile for speed trials on the Clyde, where the Lusitania was built, is longer than the nautical mile used for the same purposes more southerly. The British Admiralty knot is 6,080 feet, and the recognized knot of the United States Navy 6,080.27 feet. A knot in very general use measures 1,000 fathoms, and a fathom being 6 feet, this knot would be 6,000 feet.

In *Stahl and Eisen*, attention was recently drawn to the fact, by A. Müller of Gutehoffnungshütte, that a Girod furnace has been running for 4 years, without interruption, at the Gutehoffnungshütte Works. He claims in contrast to many early assertions that this type of furnace is distinguished by great durability of the hearth and simplicity of construction; and that the furnace has behaved admirably in practice. The advantages of the Girod electric-arc furnace are that in melting down cold charges it also works as a resistance furnace, in consequence of the passage of the current through the whole mass of scrap, and is of undeniable value as regards the rapid melting down of the charge, especially at the beginning of the smelting process. The slow and continuous leaping of the numerous arcs from particle to particle of scrap proceeds very quietly and without producing any appreciable rushes of current, the result being that the electrodes can be regulated automatically during the [illegible] operation goes on very smoothly and in conjunction with the uniformity of current distribution and generation of heat on the steel bath, and also the low tension at the poles, the difficulties of insulation are diminished.

TOWN-PLANNING CONVENTION IN CALGARY.

THE Alberta Town Planning and Housing Association will hold a convention in Calgary, June 16th, 17th and 18th. Invitations have been issued to municipalities and interested organizations throughout Canada. In connection with the convention, a city-planning exhibition will be held, the various exhibits of which will, in general, come under the following heads:

Railways.—Railway stations; railway bridges; plans of railway elevation, or depression; street railway systems; city and radial railways; street railway "fare" zones, if any.

Transportation (and Streets).—Bridges, civic and other; views of principal streets; parked streets; street plans; street planning.

Population.—Maps showing increase in area, by annexation, each increment to be distinguished by shading or color; maps showing density of population; plans showing present and prospective development; plans showing railway lines and industrial sections; factories, kind of, and factory districts.

Water Supply.—Reservoirs; stand-pipes, artistic and the reverse; pumping stations.

Sewers.—Plans showing lines of sewers; cross-section, etc., of principal sewers; sewage disposal plant.

Fire Protection.—Fire-swept areas, plans and photographs; high-pressure and low-pressure systems.

Parks and Squares.—Views in parks; parks at street intersections; maps of park systems, existing and proposed; swimming baths; monuments.

Housing.—Model houses; model subdivisions; tenements, illustrations, plans, costs and rentals; playground scenes; schools; municipal buildings, post offices, custom houses, museums, university buildings, etc.; public libraries; public markets.

Smoke investigations, and water-falls.

A feature of the convention will be the consideration of a proposed housing bill for the province of Alberta. The civic plans for Calgary and other cities of the Dominion will be on exhibition. His Honor Lieut.Governor G. H. Bulyea will begin the proceedings and various ministers of the government will take part in the deliberations. Mr. T. T. John, City Hall, Calgary, is Secretary-Treasurer of the Association.

At Nelson, B.C., a local syndicate has been formed to carry on placer-mining on Forty-Nine creek, a few miles west of Nelson, and lumber for a flume has been ordered. It is stated that the syndicate has obtained control of placer leases covering 4 miles of ground on the creek. In early years placer-miners worked successfully on the creek and obtained gold to a considerable total value.

Concerning mining in Saskatchewan, it has been reported that at Prince Albert, approximately 500 mineral claims had been staked by the middle of April at Beaver Lake since public attention was several months ago turned to that part of the province as a promising field for gold. On Saturday, April 11, registrations of 104 locations of claims were made at the Dominion Land office there, which constituted a record for any one day, but there has lately been such a rush to the new field that it is expected this will be surpassed.

A syndicate, recently incorporated under the name of the Vancouver Oil and Natural Gas Company, is carrying on careful and thorough prospecting of the oil possibilities in the flat district around Pitt River, B.C. Extending from the southern end of Pitt Lake, through towards Port Haney, they have thousands of acres of land under oil lease from the Government. Several other companies are prospecting in the Fraser delta, and quite a showing of oil indications is said to have been met with in Hatzic, further up the Fraser River from Mission, B.C.

CONTENTS OF THIS ISSUE.

THE MONTREAL ROAD CONGRESS

Road building in Quebec and Ontario was given an impetus by the First Canadian and International Good Roads Congress held in Montreal last week. Unfortunately, there were less than a score of delegates in attendance from other provinces, but the interest shown by Ontario and Quebec was manifested by an attendance of sixty-seven men from Ontario and one hundred and sixty-six from Quebec Province outside of Montreal. There were registered at the Congress one hundred and seventy-two residents of Montreal. Thirty speakers, visitors and guests came from the United States.

The Congress had the official support of the Quebec Government, being attended by the Lieutenant-Governor, the Premier, the Minister of Roads and the Deputy Minister of Roads. Many interesting announcements were made by these officials, including the fact that another ten million dollars will be voted by the Quebec legislature to lend to municipalities for road construction, the ten million dollars which was previously voted, having been practically all expended.

Hon. Louis Coderre, Secretary of State, represented the Dominion Government at the Congress, and promised that Federal aid to good roads would soon be available upon terms which he thought would be acceptable to the provinces. At the banquet Hon. Mr. Coderre and Hon. Mr. Tessier, Minister of Roads for the Province of Quebec, announced the construction of various roads and bridges amidst enthusiastic cheers.

The announcement made by Hon. Mr. Tessier that the municipalities of the Province of Quebec now owned one hundred and fifty complete road outfits occasioned considerable surprise as, so far as is known, most of these outfits were purchased without public calls for tenders.

A prominent official of the Quebec Government voiced the hope to *The Canadian Engineer* that slightly different methods will be used in the spending of the next ten million dollars to be voted by his Government. Instead of a municipality that had, say, thirty thousand dollars of money borrowed from the Government to be expended on roads, paying six or seven thousand dollars for a road outfit, and then having the roads constructed by a newly organized gang, this official urged the letting of these contracts to experienced road contractors who own their own plant.

A permanent organization of the Congress has been effected with W. A. MacLean, of Toronto, as president, to make the Congress an annual affair. Therefore, the voicing of a suggestion or two as the result of close observation of the proceedings at Montreal might be appropriate.

The Canadian Engineer has nothing but praise for the efficient work done by the executive committee of the Montreal Congress. There was nothing to be improved upon in regard to the handling of the exhibits, but the business sessions or papers of the Congress appeared, to technically trained men, to lack effectiveness in some particulars. A brief period of discussion should be provided for at the termination of each paper. There is probably always an interested listener who desires to obtain further light upon some portion of the treatment of a subject, or who has valuable opinions to express. With the session commencing at 3 p.m., however, and with seven or eight papers of varying lengths to be disposed of during the remainder of the afternoon, there is no opportunity for discussion, nor even for the speakers' best treatment of their subjects. The addition of a morning session and a

reduction by half in the number of papers for any session, would allow time for discussions.

There was some objection at Montreal to a few papers against which the charge of "commercialism" was laid. Some delegates thought that the speakers had taken advantage of the opportunity to present the methods of their particular type of pavement in an unnecessarily forcible manner. Municipal and highway engineers and road contractors, however, would not object to these papers, as much was to be learned from them. No man is so likely to be able to give valuable and comprehensive data regarding a pavement as the manufacturer of that pavement. There are only two possible objections to the so-called commercial papers: First, the possibility of unfair play by permitting a few types of pavement to be so presented while equal opportunity is not given to other types; secondly, the lack of time for an open discussion of the papers after they are presented, so that by argument and counter-argument between the manufacturers, engineers, road contractors and others who have experience in regard to the pavements, the merits and demerits of the respective pavements could be established.

From a technical standpoint, far more work would be accomplished by such a Congress were every paper to be printed and distributed about two weeks previous to the Congress, and the papers taken as read instead of being actually delivered. The entire time could then be given over to discussions and to the answering of questions by the authors of the papers. Of course, certain rules of debate, such as time limits, would be necessary, but the data that would be brought out in this way would be most valuable.

The Congress owes a vote of thanks to the American speakers who gave their time to assist the cause in Canada. Half of the speakers were guests from the United States. It is to be hoped that next year's Congress will see more Canadian engineers and officials accept the invitation to prepare papers, so as to get the benefit of their experience regarding climatic and other conditions peculiar to Canada.

STREET CLEANING AND ITS IMPORTANCE.

Many of our cities have awakened to the realization that spring house-cleaning is as much a necessity for the community as for the individual housekeeper. There appears to be a widespread appreciation in our cities that cleanliness and health go hand in hand and some are entering into the work with commendable zeal. The cleaning-up process has outgrown in numerous instances its magnitude of a few years ago, with the result that such operations cannot be carried out to civic satisfaction in a single day. The result is "clean-up week," such as the City of Montreal held during the week of May 18th.

The purity of the public water supply is generally recognized as a necessity in the promotion of public health. The same applies to the food supply, and, as is evident in cities large and small, the importance of providing a pure air supply for the community is such as to warrant continual effort in the matter of proper cleaning of streets and lanes. These become soiled and dirty as a result of, and in proportion to, their use. The materials gather thereon, partly due to carelessness, but are partly the result of conditions beyond control. They harbor large numbers of bacteria, of the nature of which little is known. While disease-producing organisms probably do not exist for long periods of time on our streets, they may be present and may thus become direct causes of infection. When dry, the material lends itself to transportation by currents of air, thus entering offices and homes, discoloring buildings and lawns, and generally affecting atmospheric conditions even to the extent of irritating the respiratory organs of citizens.

The problem of maintaining the streets of a city in a clean and healthful condition has been given considerable study in the principal European cities. The average city in this country, however, has not adequately recognized the importance of it and the work of the street cleaning department has not progressed to a careful study to determine the most efficient and economical methods of street cleaning and the nature of the results thereby obtained. The street cleaning department is not considered one of such importance as to necessitate the care and supervision of a trained expert, and where such a department exists it is generally under the direction of a man who knows little or nothing about sanitary science. The results to be expected are lack of system, inefficiency, unsightliness and danger to health.

Mr. W. H. Dittoe, chief engineer of the Ohio State Board of Health, has made a study of the methods usually followed in the cleaning of city streets and the manner in which they differ in various cities. He has stated that his investigations appear to show that the experiences of other cities are seldom taken into account. In those cities where the greatest advance has been made water is used as an adjunct, if not as a principal means of removing the material.

"The early methods of cleaning streets," states Mr. Dittoe, "utilized the machine broom, a horse-drawn vehicle with a cylindrical brush which in rotating throws the material toward the gutter. The use of this machine is often accompanied by the production of clouds of dust and the cleaned surface is not freed of the fine particles which adhere to the pavement, later to be transported by the wind. This method has been discarded in the most progressive cities in favor of more proper and advanced methods. It is now generally conceded that a street can be properly cleaned only by washing with water. Numerous devices have been proposed for the application of water to the surface of the street and all have their peculiar advantages. The European cities utilize a hose for street flushing. In the principal American cities a flushing machine is used by the operation of which the water is applied from a tank wagon under a pressure sufficient to remove the dirt from the surface. A somewhat more recent device is the combination sprinkler and squeegee machine. In the operation of this machine, the water is first applied to the surface and shortly after the wetted material is removed by a rotating cylinder fitted with rubber squeegees set spirally. The action is similar to that which takes place in the washing and drying of a window. These machines have been adopted in a number of American cities. In Berlin, Germany, an attempt has been made to utilize a vacuum machine similar in its principles to the machine almost universally used for the cleaning of carpets. This machine has not been tried out a sufficient length of time to determine its merit but it offers a method of removal of waste materials entirely satisfactory in its sanitary aspects. In general, it may be said that while marked advance in methods of street cleaning have taken place during the past few years, considerable study remains to determine the most efficient and economic methods to be used."

TECHNICAL TRAINING FOR HIGHWAY ENGINEERS.*

By A. T. Laing, B.A.Sc.,
Professor, Faculty Applied Science and Engineering, University of Toronto.

IN dealing with questions of debate one is more or less liable to be hampered with certain prejudices. The old adage that to err is human is perhaps equally clearly expressed if we say that to have a prejudice is human, and the extent to which we are so hampered is a measure of our liability to be led astray.

Coming as the writer does from an educational institution it might be supposed that he was prejudiced in a desire to promote the employment of young graduates, but while indulging a legitimate desire to give such assistance whenever possible he holds no such brief on this occasion.

Primarily the motive of the writer is to show the sympathy of the University of Toronto with this movement and to tell you something of the contributions it is making, and secondly to show a personal interest in the convention, at the same time placing some emphasis on features which he believes have an important bearing on the aims of this meeting.

Let us look briefly at what the aims are, of a course of technical training for engineers. It should greatly extend his horizon, instil a spirit of inquiry, suspend prejudice, enable him to approach a question with a clear and analytical mind. It should give him an increased sense of responsibility and more highly fit him for "the art of directing the great sources of power in nature for the use and convenience of man." A student of average endowments who has taken advantage of the instruction of an approved curriculum has been given a mental equipment which he might otherwise never acquire, and the institution which gave the instruction has been at least in a measure successful. Let us not forget, however, that there is one thing that has not yet been accomplished, the young man has not been made an engineer. That is above the might of an institution and should never be confused with its aims.

The technical graduate has only been given a start and if he is ever to become an engineer it must be through subsequent experience.

What, then, are the functions of the man thus equipped with the mental training and the subsequent experience? In brief it is the complete investigation of a given problem and with the conditions as he finds them to arrive at a solution. In other words, he must diagnose the case and prescribe the remedy, the difference between the engineer and the physician being that in many instances the filling of the prescription is the most costly part, and further, there is no specific remedy, the means employed must be governed by local conditions, and this is precisely what engineering means, the providing of one thing in one case and another thing in another to bridge over the exact same difficulty. Were it not so, all engineering problems might be reduced to a mere set of rules and all we would need would be skilled workmen to put them into execution.

Let us now see what bearing this has on the road problem. There is possibly no branch of engineering work in which a wider variety of conditions may be found. In many instances the problems demanding solution are such as to require the highest skill and experience and the conditions may alter many times in every mile of length. Among his duties might be mentioned the following:

1st. To make a survey of the road, to make profiles, establish grades, provide drainage and to relocate where necessary to avoid cuts and fills.

2nd. Prepare plans and specifications for the construction of the road and for all bridges and culverts, making ample provision for the areas to be drained.

3rd. He should be able to direct the work, provide thorough inspection, keep records of progress and all costs.

4th. He should know his machinery, its capacity, when it should be repaired, in fact mechanical appliances are employed to such an extent that he should be a mechanical engineer.

Reviewing briefly the history of road work, what do we find as touching the employment of engineers? If we go back to the time of the Romans it is not doing them an injustice to say that with all their engineering skill displayed in other works, the remarkable roads which they built were utterly lacking in the principles of sound engineering. The fact that they were able to disregard economy could scarcely be taken as an explanation for the enormous amount of labor involved in the construction of their Royal roads. There was an absence of the spirit of inquiry. They built well, but not wisely.

During the dark ages which followed the Roman period, very little road work was done. The revival of road building in France during the early part of the eighteenth century although a modification of the Roman method was marked by the introduction of more scientific principles and certainly of economy. This work was followed by that of Tresagnet, and later by Macadam and Telford and others, men of outstanding engineering ability who were among the first to employ scientific principles in the solution of the road problems of the day. Of the success of their achievements it is unnecessary to speak. The attention given to drainage, location, gradients, uniformity of cross-section, the construction of bridges, etc., were all high tributes to their engineering skill. And so with subsequent movements in road improvement we find that they have been headed by leaders in the engineering profession.

We see, therefore, the part that has been taken by technical men in the past, but where do we find ourselves in Canada to-day? There is one point at least in which we resemble the Romans, our efforts have lacked in sound engineering principles but alas the contrast—we have no roads while the Romans had. We are now on the verge of a movement which is bound to do more for our national development than all our railroads are doing. The railroads have developed the large commercial centres but they cannot supply the need of our highways. To this movement our technical institutions must contribute their share.

The place that is given to technical training in Europe will be of interest; France holds the leading place in all Europe in matters pertaining to roads. The military operations of Napoleon gave great impetus to the movement as it materially aided in the mobilization of troops. The work was recognized of such importance that it led to the creation of the Department of Roads and Bridges, which department continues to the present, and under the Minister of Public Works it has the direction of a comprehensive national road policy which has made France famous in this respect. And what do we find as an outgrowth? Recognizing the importance of trained men for the work, the School of Roads and Bridges was

*Read at First Canadian and International Good Roads Congress, held at Montreal, May 18th, 1914.

established and while the curriculum is designed to give instruction in other branches of engineering, the object for which it was designed and the outstanding feature, as name would imply, is the technical training of men for positions on staff of highway engineers.

The young men desiring to qualify for service in the department are required to take a short technical course where mathematics and science make up the major part of the work. From this they pass on to the School of Roads and Bridges and receive a three-year course of instruction in civil engineering. The vacation periods are for the greater part spent in the field under the department. It will be seen, therefore, that a very thorough course of theoretical and practical training is established.

As to the justification of the establishment of this institution one need only point to the splendid system of highways which extend throughout the republic. This influence of France in this respect has been felt in the other countries on the continent, Germany, Switzerland, Italy and others have profited by her experience, and while organization in these countries has not reached the same degree of perfection, great stress is laid on both the practical experience and the technical training of men seeking appointment as highway engineers.

In Great Britain a very different system is followed. There are many instances in which surveyors are appointed who have not had technical training, but this practice is not working out satisfactorily and the tendency now is to lay greater stress upon thorough technical training. The apprenticeship system is in vogue and the long and tedious training through which the pupil has to pass is surrounded by numerous limitations. A young lad with ordinary schooling articles to a county or municipal engineer for a period of three or four years. By hard work and study during this time he may pass the preliminary of the professional examinations and at the close of his pupilage he is qualified for appointment as an assistant and so he works his way up by stages to a chief appointment. It will be seen that by this method no standard of excellence is set, although his membership in the various professional associations will help in this respect. Furthermore, the duties of his chief may have been such that the pupil gained very little insight into road construction and management, and in the nature of the case the knowledge of the subject gained must be limited to the field within which his experience lay.

The consensus of opinion, however, is in favor of a thorough technical training and a recognition of its importance is given in the fact that a student with an engineering training may reduce the period of pupilage to one year.

Coming to this continent, what do we find? Alas in the past there has been little disposition to recognize the office of a highway engineer. An assumption far too common has been that anybody can build roads, and what is the result? Either that illusive personage has given up the job or he has been bluffing, for we are still, in a large measure, without roads.

In both Canada and the United States many municipalities have paid heavily to prove that the township clerk, or the assessor or some other official could not build a culvert, a concrete bridge abutment or a road that would last, and many a lamentation has gone up that enough money has been spent to have paved the road in gold and still the road is bad. It is true that engineers, even the best of them, at times may make mistakes, but it is safe to say that their achievements in other lines is sufficient to warrant the recognition of their services in the solution of the problems in highway work.

With the changes that have been brought about in recent years through the introduction of the motor-driven vehicle the problems have become more complex and our treatment of the question has not kept pace with the demand, due largely to a disinclination to abandon old methods.

That the universities of this continent are not lax in dealing with this question may be seen by a brief review of what is being done. In the United States remarkable advancement has been made. In nearly every technical institution where a course of civil engineering is taught the subject of highway engineering is given a prominent place, and in many cases is made a major subject of the final year. Five years ago less than half of these institutions touched the subject. The Department of Public Roads at Washington, through the efficient directorship of Logan Waller Page, has also given a great impetus to the training of young men. By giving a special course of instruction in the department and then placing these men in charge of work on the field a practical demonstration has been given of the value of such training.

In Canada, we are glad to see that a like recognition of the subject is being given. It is not possible, at this time, to go into details but we are pleased to note that highway engineering is given a prominent place in the curricula of nearly all the universities and technical colleges throughout the Dominion. In this, Laval University has been the leader, having begun such a course over twenty years ago. In the University of Toronto the subject is combined with sanitary engineering in the fourth year of the civil engineering course. The time is devoted to a lecture and reading course dealing with the design, drainage, foundation and the construction of all types of roads from the ordinary clay road up to high-class city pavements. A lecture course on the geology of road metals, a lecture course on municipal structures, including highway bridges, culverts, retaining walls, etc., a laboratory course for the examination of the properties of sands, gravels and the various kinds of rock employed in road construction and also for the physical properties of bituminous materials, all of which have a direct bearing upon the efficiency of the young engineer.

One feature of this work is worthy of special mention. Laboratory investigations will continue to form an important adjunct to our highway work and it is of utmost importance that the engineer in charge of work should know how to interpret such reports and there is no way in which he can do this more intelligently than by having conducted a series of experiments himself.

In view of the facts cited with respect to practice followed in Europe, what should be our attitude in Canada? Can we afford to disregard the features in training to which they in Europe give such prominence? Certainly in many respects our problems are beset with conditions more difficult and such as tax to the resources of our best engineering skill and ability, and this congress will have conferred a lasting benefit on our community if it does nothing more than to educate public opinion to a fuller recognition of the importance of utilizing the services of our technically trained young men in the improvement of our highways.

This is mentioned as one feature of our pressing needs, not unmindful of the fact that there are others. As much more might be said regarding a systematized national policy, but even this must be organized and put into execution by engineers who can fully grasp the problem. His status must be recognized and the rewards for his services commensurate with the high office he is called on to fill.

ROAD CONGRESS AT MONTREAL.

THE First Canadian International Good Roads Congress was held in Montreal last week. It was marked by the attendance of a goodly number of men whose prominence in road matters in Canada and the United States is well known, their presence serving as an indication of their optimistic feeling and their eagerness to be of assistance on this particular occasion. The Good Roads Show was well patronized and the entire arrangement was such as to provide every delegate with an opportunity of taking full advantage of the entire proceedings of the convention.

The opening session on Monday afternoon was largely devoted to inaugural addresses. Mr. U. H. Dandurand, chairman, in his opening remarks, bore out the good and substantial aims upon which the Congress has been founded. Sir Francois Langelier, Lieut-Governor of Quebec, and Sir Lomer Gouin, Premier of Quebec, attended this opening session and took part in the ceremonial speeches. The former outlined the condition of the roads in Quebec as it was many years ago, and traced the development of the idea that good roads were a necessity from the time when the people in Quebec Province looked only to the St. Lawrence River and other great water routes, as well as to the snow roads of winter, for their means of transportation. The Premier spoke of the aims of the Province of Quebec in the matter of good roads, and indicated that a very substantial progress was being made. They had spent seven or eight millions of dollars on roads and had some exceedingly good roads to show for it.

Hon. Louis Coderre, Secretary of State, voiced the hope that the Federal and Provincial governments would come to an early arrangement respecting a grant for road construction and improvement.

The next address was that of Mr. W. A. McLean, Provincial Highway Engineer for the Province of Ontario, and president of the American Road Builders' Association. Mr. McLean spoke on highway legislation. In this connection he maintained, as principles of highway legislation that could have a general application, that cities should assist in the payment occasioned by the building of public highways; that municipal self-administration should be encouraged, and that the central administration should be relied upon for assistance when circumstances demanded.

Dr. E. M. Desaulmiers, M.L.A., Chambly County, St. Lambert, P.Q., spoke briefly concerning road legislation for the Province of Quebec compared with other provinces.

Mr. A. N. Johnson, chief state highway engineer of Illinois, presented a very interesting paper entitled "Planning of System of Public Roads," but owing to the lateness of the hour Mr. Johnson was obliged to follow the example of the previous speaker by reading only brief portions of his address. His chief contention was that the first necessity in road construction was to make a plan of the work to be done over a wide area, so that in future years whatever work was done they would be working on the recognized system which, when completed, would be twice as valuable on account of its unity.

In the evening and on other evenings throughout the convention special illustrated lectures were given by the manufacturers of road-building materials and machinery, represented at the Congress. They were well attended and displayed many interesting features in the solution of problems commonly met with.

The next session of the Congress took place on Tuesday afternoon. In his opening address, Mr. Dandurand reviewed the work of the previous day. He introduced the subject of a permanent organization. Later in the afternoon he brought the subject again before the meeting, putting it in the form of a motion, which was unanimously carried. The following committee was appointed to make a report to the Congress: Mr. Geo. A. McNamee, secretary-treasurer of the Good Roads Congress; Mr. W. G. Robertson, secretary of the Canadian Automobile Federation; Mr. I. S. Pennybacker, secretary of the American Highways Association, and Mr. H. W. Pillow, president of the Automobile Club of Canada.

In an address entitled "Important Considerations Entering Into the Selection of Pavements for Roads and Streets," Mr. W. H. Connell, chief of Bureau of Highways, Department of Public Works, Philadelphia, emphasized the necessity for trained men for the construction and maintenance of highways. Enormous sums of money had been uselessly expended by those who employed untrained men not only to construct but to maintain their roads. Next in importance to the personnel, careful consideration should be given to the drainage, the present and probable future traffic, foundation gradient, social and sanitary conditions, and wearing surface. Rigid inspection of a road in the process of construction was an absolute necessity.

Mr. E. A. James, consulting engineer to the York County Highway Commission, presented a paper, read by Mr. W. Huber, of the Ontario Department of Public Works, on "Maintaining Macadam Roads." It was claimed that nine-tenths of the objections to macadam roads arose from an improper observation of the rules which govern their maintenance, rather than from difficulties of construction. A list of the various agencies tending to deteriorate such roads was given prominence among which were mentioned narrow tires. The paper favored the patrol system of maintenance and expressed both the statute labor and the contract labor systems of maintenance as generally satisfactory.

"Points Worth Knowing in Connection with Road Improvement," was the subject dwelt upon by Major W. W. Crosby, consulting engineer, Baltimore. Any comprehensive scheme, according to the speaker, necessitated the selection of the most important roads and also the selection of methods and means to be employed. The construction of good roads should be regarded as an investment which must show both direct and indirect benefits. Borrowed money should be used entirely for construction purposes, and the cost of maintenance should be guaranteed out of annual levies. Major Crosby emphasized the fact that there was no such thing as a permanent road. Every road requires maintenance and careful attention, no matter of what type it may be constructed.

Lieut.-Col. W. N. Ponton, honorary president of the Ontario Associative Boards of Trade, read a most interesting paper on good roads as a factor in the progress of cities and towns. The speaker did not endeavor to present anything in the nature of a technical paper, but his address was a rousing elucidation of the effect upon the country which is sure to follow the establishment and proper maintenance of good roads. He suggested that the Congress should be made a constant and permanent element of influence and that it should appoint a committee to lay before Parliament a well-digested plan for accomplishing the best work by the best methods.

Mr. R. Lehmann, engineer of the French Government Service, New York City, gave a very interesting address

in French on the administrative organization by which French roads are constructed and maintained. As numerous references had previously been made to the excellent roads in France, the observations of Mr. Lehmann were followed with close attention.

On Tuesday evening a banquet in honor of the guests of the Congress was held at the Hotel Windsor, and was attended by approximately 100 delegates. The speeches were such as to arouse enthusiasm in the building of roads, while several announcements of importance were made pertaining to appropriations in Quebec for the same.

On Wednesday morning tours of investigation were held whereby the delegates had an opportunity of seeing for themselves roads and streets in and around Montreal and the adjoining towns.

At the Wednesday afternoon session Mr. C. L. Shorey, of Beaconsfield, P.Q., began the proceedings by a brief talk on road improvement in that town.

"Concrete Roads and Streets" was the subject of a paper by Mr. L. R. Ferguson, assistant secretary, Association of American Portland Cement manufacturers, Philadelphia.

Mr. Ferguson's paper dealt largely with the cost of construction of cement roads as compared with that of other types, and dwelt upon the relative costs of maintenance. He spoke of the burdening of municipalities to the extent of $650 to $1,000 per mile per annum in the case of several types, whereas the cost of maintenance of the cement roads was placed by him at from $25 to $50 per mile per annum.

When the bonds matured, the latter road still remained in good condition, whereas other roads were frequently found to require replacing before the expiration of the usual 20 years. Another advantage voiced was the low crown of the concrete roads which reduced the danger from side-slipping, thereby being a distinct advantage both to horse and automobile traffic.

Professor Arthur H. Blanchard, of the Department of Highway Engineering of Columbia University, New York, gave an illustrated talk on modern bituminous surfaces and bituminous pavements. He dealt to considerable length with the construction of such roads and the improvements which the practice of later years have presented. Various types of machinery were illustrated and the most satisfactory methods of construction and maintenance clearly outlined. Professor Blanchard showed a number of interesting views of roads and road work in America, and in England, France and Germany.

Mr. A. T. Laing, of the Department of Highway Engineering in the University of Toronto, read a paper entitled "Technical Training for Highway Engineers," in which was clearly brought out the value to the road movement which would accrue from the courses of instruction that were being given at the principal universities and colleges throughout the Dominion.

"Road Designing" was the subject of a paper by Mr. R. A. Meeker, engineer, Department of Public Works for the state of New Jersey. In the course of his paper he emphasized the importance of selecting the best route and also the importance of proper grading. Mr. Meeker reiterated the words of the prophet Isaiah who, over 2,600 years ago wrote, "Every valley shall be exalted and every mountain and hill shall be made low, and the crooked shall be made straight and the rough places even."

Mr. Will P. Blair, secretary, National Paving Brick Manufacturers' Association, read the next paper, which was entitled "The Economy of the Brick Highway." Mr. Blair based his remarks upon the value of making careful comparisons with respect to the relative merits of paving material and outlined the elements in the economy of the road and the relation which they bear to each other.

"The Relation of the Technical Press to the Good Roads Movement," was commented upon by Mr. H. Irwin, editor of *The Canadian Engineer*. His paper dealt with the classification of the engineering literature at the service of the man associated with road administration and development. Respecting the selection of technical books on road work, he emphasized the value of dependence upon unprejudiced and straightforward reviews which are to be found in the recognized technical journals published from time to time. He outlined the growth of engineering literature on the subject of roads and suggested a plan whereby the road man could equip himself with a valuable library of information upon his subject. He strongly emphasized the value of the card index system in the preservation of articles of interest. The road man was warned against limiting the scope of his reading to that which pertained only to his immediate needs. It was claimed that the successful road engineer should read much more than that which deals with his own special work.

At Thursday's session Mr. O. Hezzelwood, chairman of the Canadian Automobile Federation, presented the first paper, which was entitled "The Relation of the Motorist to the Good Roads Movement." Following him, Mr. H. W. Pillow, president of the Automobile Club of Canada, made some observations and some valuable suggestions regarding the road movement.

The secretary of the American Society of Engineers, Architects and Constructors, Mr. T. Hugh Boorman, presented a paper entitled "Modern Road Construction in the United States and England." Mr. Jean De Pulligny, chief engineer, bridges and roads and the director of the French Mission of Engineers to the United States, spoke concerning the International Good Roads Congress, while Mr. J. W. Levesque, of Montreal, gave an address entitled "The Improvement of Rural Roads as a Source of Considerable Economy to the Farmer.

Another paper, entitled "Automobile Organization and Harbor Improvement," was read by Mr. W. G. Robertson, secretary, Ontario Motor League.

Mr. H. M. Capron, of Chicago, addressed the Convention on the subject of the bulk handling of cement.

Mr. Lucius E. Allen, consulting engineer, Belleville, Ont., read the last paper of the session, entitled "The Construction of Modern Highway Bridges."

Toward the close of the Congress the committee which had been appointed a few days before to make a report respecting a permanent organization, brought in their report, which was received and unanimously adopted. The officers elected were: Honorary President, A. U. Dandurand, Montreal; President, W. A. McLean, Toronto; First Vice-President, D. Michaud, Quebec; Second Vice-President, O. Hezzelwood, Toronto; and Secretary, G. A. McNamee, Montreal. Directors: H. W. Pillow, Montreal; W. J. Kerr, Vancouver; Col. W. N. Ponton, Belleville; Ald. R. J. Shore, Winnipeg; R. S. Henderson, Winnipeg, and J. Duschatel, Outremont, Que.

The list of directors has been left incomplete in order that the present executive may add to their numbers representative men from all parts of the Dominion.

Among the delegates who attended the convention from the United States were the following: J. S. Barron, Baker & Barron, New York; Col. T. H. Boorman, secretary American Society of Engineers, Architects and Con-

structors, New York; C. C. Blair, Youngstown, Ohio; Prof. A. H. Blanchard, Columbia University, New York City; A. G. Batchelder, New York; M. M. Campbell, C.E., American Road Building Association, New York; Major W. W. Crosby, Baltimore, M.D.; W. H. Connell, Philadelphia, Pa.; J. R. Draney, General Sales Manager, United States Asphalt Refinery Co.; W. DeWind, Austin Mfg. Co., Chicago, Ill.; A. N. Johnson, Chief State Highway Engineer, Springfield, Ill.; R. Lehmann, Engineer of French Government Service, New York; R. A. Meeker, State Highway Engineer, Plumfield, N.J.; A. F. Masury, New York; I. S. Pennybacker, Washington, D.C.; M. D. Powers, New York; E. S. Powers, New York; O. R. Parry, New York; Wm. A. Perkins, Connsant, Ohio; H. K. Salmon, Netcong, N.J.; Gordon Smith, Albany, N.Y.; H. Spencer, New York; Geo. D. Steele, Germantown, Pa.; H. C. Tattersall, The Troy Wagon Works Co., Troy, Ohio, care Wm. McNally & Co., and Maurice R. Young, New Jersey, Robeson Process Co.

Four hundred and fifty delegates, guests, speakers, exhibitors, etc., registered at the Congress. Of these, one hundred and seventy-two were from Montreal and one hundred and sixty-six from Quebec Province, outside of Montreal. One hundred and twelve registered from without the Province of Quebec, these being divided as follows: Ontario, sixty-seven; New Brunswick, seven; Manitoba, four; Alberta, two; Nova Scotia, two; India, one; United States, twenty-nine.

The exhibition of road machinery and materials which was held in connection with the Congress was very well managed and made a good impression upon those in attendance. It compared very favorably indeed with any similar exhibition that has ever before been held in every respect, excepting, of course, in the number of exhibits. Not only was the exhibition very pleasing to the eye, but to those who took the time to study carefully the machinery and materials presented and to listen to the information given by those in attendance at the booths, there was much to be learned.

Asphalt and asphaltic road oils were exhibited by the Aztec Oil and Asphalt Refining Company of Canada, British American Oil Company, Elder-Ebano Asphalt Company, Limited, and Imperial Oil Company. Tarvia and Barrett Specification Roofing were exhibited by the Paterson Mfg. Company. The Canada Creosoting Company, Limited, exhibited wood paving blocks and methods of creosoting railroad ties and bridge timbers. The Canada Cement Company, Limited, exhibited methods of concrete construction for roads and streets, in addition to a number of novel ways of using cement. The Dunn Wire Cut Lug Brick Company and its licensees had a joint exhibit.

Among the machinery manufacturers, the largest exhibits were those of Mussens, Limited, and of the General Car and Machinery Works, both of these firms exhibiting some machinery of almost every type necessary for road construction.

The Canadian Fairbanks-Morse Company, Limited, had a large exhibit of mixers, pumps, Koppel dump cars and other contractors' equipment.

Road rollers were exhibited by Mussens, Limited, General Car and Machinery Works, Albion Motor Car Company of Canada, and the J. I. Case Threshing Machine Company. Sawyer-Massey Company had a booth, but were unable to get one of their rollers to Montreal in time for the exhibition.

Foss and Hill Machinery Company exhibited London concrete mixers, sidewalk forms and other contractors' equipment. The Pedlar People, Limited, constructed within their booth a Toncan metal garage, within which they exhibited corrugated culverts, Clinton wire cloth, ferro-dovetail and their various other lines. Corrugated culverts were also exhibited by the Canada Ingot Iron Company.

Baker-Barron, Inc., exhibited scrapers, graders and other road machinery. Alex. Bremner, Limited, exhibited builders' materials and municipal supplies. J. H. McCarty & Company exhibited Waterous road machinery. William McNally & Company, Limited, exhibited a Troy dump wagon and contractors' supplies. Jones & Glassco had in their booth a Foden steam truck.

The Decauville Flexible Armor Company of Canada exhibited a patented method of reinforced concrete brick construction for protecting embankments. Thomas Davidson Mfg. Company, Limited, showed samples of street signs, house numbers and other enameled steel products.

The technical and trade press was well represented, as there were exhibits by Good Roads, Canadian Municipal Journal, Good Roads of Canada, Contract Record, and *The Canadian Engineer*.

INTERNATIONAL ENGINEERING CONGRESS, 1915.

Among the general subjects to be treated before the International Engineering Congress, 1915, probably the one having the broadest interest is that of Materials of Engineering Construction, which enters into all phases of engineering activity. The list of topics which will be treated in this section is as follows:—

(1) Timber.
(2) Preservative Treatment of Timber.
(3) Substitutes for Timber in Engineering Construction.
(4) Brick in Engineering Structures.
(5) Clay Products in Engineering Structures.
(6) Probable and Presumptive Life of Concrete Structures made from Modern Cements.
(7) Aggregates for Concrete.
(8) Slag Cement.
(9) Waterproof Concrete.
(10) Cements containing Additions of Finely Ground Foreign Material.
(11) Economics of the World's Supply of Iron.
(12) The Life of Iron and Steel Structures.
(13) The Employment of Special Steel in Engineering Construction.
(14) The Place of Copper in the Present Engineering Field, and the Economics of the World's Supply Thereof.
(15) Alloys and Their Use in Engineering Construction.
(16) Aluminum in Engineering Construction.
(17) The Influence of the Testing of Materials upon Advances in the Designing of Engineering Structures and Machines.
(18) Cement Testing.
(19) Testing of M[illegible]
(20) Testing Full-Sized Members.
(21) Proof Testing of Structures.

The papers to be presented from the United States have already been arranged for from the recognized leading authorities on the various topics. Arrangements for the papers from authors in other countries are being rapidly concluded, and the aggregation of papers which will be presented will constitute [illegible] review of the field [illegible] of the highest value.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

CONTENTS.

BOOK REVIEWS.

Heat.—By E. M. Shealy, Assistant Professor of Steam Engineering, University of Wisconsin; published by McGraw-Hill Book Co., New York City; 262 pp.; 110 illustrations; 6 x 9 in.; cloth. Price, $2. Reviewed by R. W. Angus, Professor of Mechanical Engineering, University of Toronto.

This book is one of the series prepared by the Extension Division of the University of Wisconsin and deals with the application of heat to various types of machinery, such as steam and gas engines, air compressors, etc. It is evidently written more from the view of the practical than of the technically trained man, as the use of formulas has been very largely avoided and where they do appear, they are not of a complicated nature, so that they are easily understood.

The first six chapters deal with the general principles required in studying the action of heat—e.g., temperature, work and power, transferring and measuring heat, as well as its generation and effect on gases. In many cases the discussion is illustrated by a simple physical experiment showing the meaning. Some attention has been given to insulation and heat transmission, through various substances, coefficients being supplied for practical application.

After the preliminary chapters the book follows along the same general lines as other books on applied thermodynamics except that the treatment is rather more elementary than is usual. Chapters VII. to IX. discuss the working fluids; gases and vapors, and include a table of the properties of vapors. The chapters on the steam engine are too brief and attempt to deal with too much—e.g., the Carnot's Cycle is dealt with in one paragraph and would not be of much help to a beginner whose ideas are not well formed.

The parts dealing with air compressors, gas engines and refrigerating machines are also brief but contain some very helpful material.

The work concludes with a chapter on house heating and would prove of help to men desiring an elementary general knowledge of the important applications of heat in the production of power, etc.

Engineers' Costs and Economical Workshop Production. By Dempster Smith and P. C. N. Pickworth. Published by Emmott & Co., Limited, Manchester, Eng. 248. pp.; illustrated; 6 x 9 ins. Price, $1.25.

Shop superintendents and others responsible for carefully watching and keeping down costs in engineering workshops will appreciate the truth of a statement in the first chapter of this book which says "The acuteness of present day trading, however, has removed, in the majority of cases, the happy days of ample margins and has produced a state of affairs in which only by accuracy in the estimation of costs can a profit be relied on."

The book has avowedly been written "from the engineer's standpoint rather than from the accountant's."

After treating in the earlier chapters of the various qualities and grades of pig iron, wrought iron, steel and copper in commercial use, the authors pass on to specifications of materials as formulated by the British Engineering Standards Committee, thence to wage systems, shop qrganization, the time necessary for performing various operations, inspection work and classes of it, establishment charges, reserve maintenance and depreciation, freight charges, shipment of goods, cost keeping and estimating.

The foregoing shows that all the essential ground relating to cost of production has been covered and perusal of the book leads one to believe that the writers' know the subject with which they are dealing. It is evident that a great deal of time and care has been expended on this work, the subject matter is well put together and the diagrams are very clearly drawn. Avoidance of very abstruse mathematics is perhaps another point which will form a recommendation to some.

Practical Sanitation.—By George Reid, M.D., University of Cambridge; 17th edition. Published by Charles Griffin & Co., Limited, Exeter Street, Strand, London; 354 pp.; illustrated; 5¼ x 7½ ins.; cloth. Price, $1.50 net.

It will be noticed that this book is in its 17th edition and has evidently, therefore, filled a want in Great Britain.

Like most of Messrs. Griffin's publications, the book is a good one, and will be found to contain much information useful to "Insanitary Spectres" (as the maid of all work termed them), and others interested, for whom it has been written.

The first half deals with water supplies, ventilation, drains and plumbing work generally, and examples of both good and bad work are given; owing to differing methods of working, and to the fact that some of the appliances used here are not quite the same as those employed in the old country, portions of this section will hardly apply here, but this does not detract from the value of the book as a whole. Since the author is a medical man he has been able to incorporate into the later portions of the book a good deal of information regarding infection and disinfection, food, etc., which is well put together and apparently up-to-date.

Hydraulics. By Ernest H. Sprague, A.M.I.C.E., Assistant at University College, London; formerly Professor of Engineering at the Imperial Chinese Railway College, Shan Hai Kuan; 184 pages; 80 figures. Cloth, 4¾ x 7½-in. Published by Scott, Greenwood and Son, London, Eng. Price $1.

The author of this little book states that it has been compiled from his lecture notes and that it is intended to be

a text book for students and engineers. The title itself has been somewhat misapplied as the scope which the book includes is rather limited and does not cover the subject of hydraulics in any way exhaustively. It will be found, nevertheless, to be a concise, well-balanced text supplemented by a collection of very useful data for hydraulic engineers.

The chapters have the following arrangement: Introduction and principles of fluid pressure; liquids in motion; discharge through orifices, weirs, etc.; flow in pipes and channels; pressure of water and application to motors; pumps. The text is supplemented by 143 examples which can be strongly recommended to the student of hydraulics. The illustrations which the book contains are not well drawn, and are lacking in uniformity throughout. Otherwise they are of great value to the text.

The author has made free use of the Calculus, but his deductions have been carefully made and no engineer is apt to consider that he has over-rated its value to the subject at hand.

Practical Locomotive Operating.—By Clarence Roberts, Assistant Road Foreman of Engines P.R.R., and Russell M. Smith, Air-Brake Instructor P.R.R. Published by J. B. Lippincott Company, Philadelphia, Pa. 292 pages; fully indexed; 92 illustrations; 5 inserts. Cloth. Price, $2. Reviewed by Geo. S. Hodgins, Mechanical Engineer, Transcontinental Railway, Ottawa.

This book is a "practical" book written by practical men for practical men. The subjects taken up are those that locomotive enginemen ought to know, and those who take a lively interest in railroad work, ought also to know. In Part I., the classes of locomotives are given, and the processes involved in locomotive operating, the power of locomotives, train resistance and locomotive efficiency are explained.

The processes involved are combustion, the generation of steam, its utilization and the impulsion, by adhesion, of the driving wheels. Some remarks are made about mechanical stokers. The point is clearly brought out, that such a stoker is not intended to surpass hand-firing in the matter of economy, it takes its place, and it is a most important place, when it does work far beyond the physical ability of the fireman to do.

The whole rationale of steam generation is gone into and a table of the properties of saturated steam is given. The authors admit that it is not definitely known how fast heat transfer through the firebox plates takes place, but good practice has at least empirically (that is by trial and experience) found that if the heating surface goes below 60 or 65 times the grate area, heat will be lost, as there will be more than the plates can transfer to the water. If the ratio between the two is much greater, the additional efficiency gained will be too small to compensate for the extra weight and cost. Next comes tractive effort and horsepower. The correct formulas are given and the whole matter is very clearly set forth. The important part played by adhesion is explained. This matter of adhesion is not, as a rule, made to occupy the position that it should have, and that its close connection to tractive effort, entitles it to.

The friction of the locomotive itself receives attention, and train resistance formulas are given and examples worked out. There is one ratio constantly given in technical papers which needs explanation. It is that got by dividing the tractive effort by the heating surface. To many this seems like a meaningless performance, but its value becomes clear, when, as the authors point out, the available tractive effort decreases while the speed increases, because at high speeds the cut-off is early and the mean effective pressure in the cylinders is thereby reduced. Take a given locomotive for example. Its wheels and cylinders remain constant, and the mean effective pressure is the variable. As the mean effective pressure changes, the tractive effort changes also. Several curves are plotted on a diagram and these show how this takes place. When the horsepower is calculated, mean effective pressure and speed are the two variables, and so at the highest speeds the indicated horsepower is a maximum, though the tractive effort is quite small as compared with slow speed. Tractive effort is drawbar pull, less internal friction, but it does not of necessity imply motion, while horsepower is the rate of doing work, that is the drawbar pull actually producing motion. Work is spoken of here in the mathematical sense of pressure acting through space or against resistance.

It is not our purpose to give a close or complete analysis of the whole book, or go into every detail. We have instanced these points to emphasize the plain practical nature of the work. Under the head of Classification of Locomotives Part II., the ordinary types come in for definite treatment, and the compound is dealt with in detail. The subject is well illustrated and the reasons for the various operations involved are told in plain language. There is a table of dimensions and characteristics in which a large number of locomotives, running on many railways, are given.

Part III. opens with a general and easily-understood explanation of physics, mechanics, dynamics, heat, temperature, etc., etc. Under the head of chemistry coal is defined technically, and its composition, heat values, etc., are made clear. The meaning and use of the British Thermal Unit is important, as many fuels are bought on the basis of the heat units they will give. The volatile and solid constituents of coal are distinguished. It is easy to see that carbon mon-oxide (CO) is the result of incomplete combustion, and this results in the loss of heat which would otherwise be given off, if carbon di-oxide (CO_2) was formed. An interesting proof of this may sometimes be seen by looking at the top of chimneys of rolling mills, etc. When carbon mon-oxide is formed in the furnace it is carried up the flue as very hot smoke. At the top of the chimney when meeting the air, it bursts into flame, and CO burns to CO_2, thus completing the combustion without raising the temperature of the furnace. The loss thus becomes actually visible.

Part IV. deals with steam, states Boyle's or Mariott's law, and gives a comprehensive table of physical properties of saturated and superheated steam. The generation of steam and the work done in its formation are interesting subjects and the expansion of steam and cylinder condensation naturally follow in the book. The advantages of superheated steam are set forth and it easily becomes clear to the reader what happens and where economy comes in, with cylinders which may be supplied with superheated steam, approximately to a perfect gas with margin enough to meet inevitable cooling; and the same cylinders filled with saturated steam close to the dew point and which is little better than high pressure fog. Part V. is devoted to boilers, and in this section classes and types appear, construction features, superheaters, draft appliances, safety devices, parts and appurtenances; with boiler power data, and it concludes with remarks on injectors.

Part VI. takes up lubrication and lubricants. Part VII. follow with cylinders and valves and valve gear. Part VIII. is eminently practical and deals with running and firing. Here the rationale of the whole process of firing and running an engine with care and economy is brought out. The values of the volatile hydro-carbons and the fixed carbon are given, as they theoretically are, together with the results

of experience and test. These facts are placed before the reader in concise form, and the why and wherefore is followed out to the end.

Part IX. deals with disorders, deterioration, pounds, blows, and breakdowns. Part X. takes up appliances and parts such as the brick arch, injectors, water gauges, lubricators, pop safety valves, flexible staybolts, and all the many etceteras that should be understood and studied by all those running, repairing, caring for, or designing engines. Part XI. is concerned with operating conditions, qualifications and responsibilities of the operating staff. The selection of men, co-operation between enginemen, health of employees, first aid, etc., and it closes with a series of questions on the subjects with which the book deals in detail. Part XII. gives the United States Federal laws respecting boilers and safety appliances.

The work is "a new book" in more senses than one, and may be said to be the latest word on running and firing. Locomotive engineers and firemen spend about half their time on an engine and it is therefore important for them to become familiar with all the parts and appliances of the machine, and to know the latest approved practices in running and firing, particularly about those types of engines equipped with superheaters, brick arches and improved valve gears. These appliances have caused a great increase in locomotive efficiency, and for their proper operation, a demand has been created for progressive locomotive engineers and firemen, possessing a high standard of intelligence. This book contains information that engineers and firemen ought to have, in order to pass examinations and fit themselves to do good work. The study of this book will encourage them to think and to develop their faculties by solving, or endeavoring to solve, the various problems which daily arise in locomotive operating. The scope of the work is designed to teach the high value of efficiency; for the knowledge of the science of locomotive running gives to the man possessing it, a legitimate feeling of security and self reliance and he is therefore worth more to himself and to the company he serves.

Alloys and Their Industrial Applications. By Edward F. Law. Second Edition, published by Charles Griffin & Co., London; pp. 332; 6 x 9 ins.; cloth. Price $3.50 net. Reviewed by A. S. L. Barnes, Hydro-Electric Power Commission of Ontario.

The main purpose of this book is indicated in the prefact to the first edition, to be the summarizing of "the existing state of our knowledge of mixed metals, paying special attention to the general principles and essential facts. . . . An attempt has also been made to present the subject in such a manner that it will be intelligible, not only to the student but also to the manufacturer and the engineer, for whom the volume is primarily written."

The author was at one time assistant to that master of metallurgy, the late Sir William C. Roberts-Austen, who has contributed so largely to our knowledge of metals, and particularly of alloys.

If association with so great a mind be of any benefit we should expect to find the subject in the present work dealt with in a thorough fashion; in this the writer has not failed, but has presented a vast amount of detailed and interesting information in well arranged form.

A great many problems connected with alloys still remain unsolved, and there is a wide field for research still open in connection with them.

Engineers with some knowledge of electricity will be interested in the fact that while, as is well known, the pure metals all show a tendency to become perfect conductors of electricity at the absolute zero of temperature, alloys by no means do so; this difference in behaviour is said to be due to the fact that in the latter electric currents circulate within the materials owing to the presence of dissimilar metals, an opposing electro-motive force being set up, thus making their ability to oppose the passage of an external electric current through them greater than is the case with pure metals. The union of certain metals bringing about a great evolution of heat is a fact now familiar to all through the well-known "thermit" process so largely employed for railwelding, etc., but a combination of metals is referred to in this volume in the union of which there is an absorption of heat to such an extent that the temperature of the mixture falls from +17°C. to —10°C., or a drop of nearly 50°F. The book contains tables setting forth the properties of many different alloys, together with, in some cases, remarks as to their suitability for certain purposes. Chapters on brasses, bronzes, aluminium alloys, silver and gold alloys, iron and miscellaneous alloys and analysis are given as well as much information as to methods of investigation, influence of temperature, etc. As to the last named item, however, it is remarkable that a vain search was made through the whole book for any information relating to the temperature co-efficient of expansion of alloys; apparently this point has been completely overlooked, as it can hardly be argued that it is one of no importance in practical work—in some cases it is necessary to have this information.

One unusual, though by no means objectionable feature, may be noted, and that is the insertion of a brief bibliography at the end of some chapters relating to their subject-matter, instead of putting them all together at the end of the book.

PUBLICATIONS RECEIVED.

Nova Scotia Steel and Coal Co., Limited.—Report of the thirteenth annual general meeting of shareholders, held on March 25, 1914.

Bathurst District, New Brunswick.—Memoir No. 18-E, by G. A. Young; issued by Geological Survey branch, Department of Mines, Ottawa. A report on the Bathurst District, New Brunswick, and the Nipisiguit iron ore deposit together with maps.

Geology, and Mineral Deposits of the Tulameen District, B.C.—Memoir No. 26, by Charles Brock, and issued by the Geological Survey, Department of Mines, Ottawa. An illustrated report on the general characteristics, geology, and mineral deposits of the Tulameen District, B.C.

Some Myths and Sales of the Ojibwa of Southeastern Ontario.—Collected by Paul Radin and issued by the Geological Survey, Department of Mines, Ottawa. This interesting memoir contains myths collected by Mr. Radin in connection with the study of the ethnology and linguistics of the Ojibwa of Southeastern Ontario.

Proceedings of the First Annual Industrial Safety Conference. This conference was held at Reno, Nevada on January 26 and 27, 1914, a report of the proceedings being published by the University of Nevada. This report includes papers, talks, and discussions by prominent members of the conference, in connection with the "Safety First" movement in Nevada.

The Quantity System of Estimating.—By G. Alexander Wright, President of the Technical Society of the Pacific Coast. This leaflet is a brief treatise on the quantity system of estimating, a subject in connection with which Mr. Bell has devoted considerable thought and activity. By this system, Mr. Bell maintains, present estimating and contracting methods will be greatly bettered.

Clay and Shale Deposits of New Brunswick.—Memoir No. 44, by J. Keele, published by Geological Survey, Department of Mines, Ottawa. This report is on the result of investigations to determine whether the clay and shale deposits in New Brunswick were of sufficient extent to be of economic value, or of use to manufacturers of burned clay wares, for structural or other purposes.

Electrical Furnaces for Making Iron and Steel.—Bulletin No. 67 of investigations carried out by the Bureau of Mines with a view to increasing safety efficiency and economic development in metallurgical industries. The application of electricity to various processes, and especially to those in the manufacture of iron and steel, is given special attention. This bulletin gives some of the results of work already done, a brief historical review of the development of electric furnaces for making iron and steel, and discusses the problems that remain to be solved in the use of electric furnaces for the smelting or iron ores and the production of pig iron at a profit on a commercial scale.

CATALOGUES RECEIVED.

Rope Drives.—An 8-page pamphlet issued by the Mesta Machine Co., Pittsburg, Pa., and describing installations of rope drives for almost all conditions of service.

Sewage Disposal Plants.—Bulletin, series "G," No. 1, describing apparatus, equipment, and complete plants for sewage disposal. Issued by the Sanitation Corporation, New York.

Watthour Meters.—Circular No. 1137 containing 24 pages descriptive of watthour meters for alternating and direct currents. Issued by Canadian Westinghouse Co., Limited, Hamilton, Ont.

Turbine Pumps.—Bulletin No. 2001, issued by Canadian Allis-Chalmers, Limited, descriptive of the construction, working principles and applications of the Mather and Platt patent high-lift turbine pumps.

Axtec Asphalt.—The Interocean Oil Co., of New York, have issued a well gotten-up catalogue describing Aztec asphalt, its composition, use and advantages. This catalogue is well illustrated and contains 28 pages.

Cochrane Meters.—Engineering leaflet describing the practical uses and advantages of Cochrane meter heaters, feed water meters, and independent meters. Issued by the Harrison Safety Boiler Works, Philadelphia, Pa.

Iroquois Road and Street Paving Machinery and Tools.—A 16-page catalogue illustrating and describing road rollers, bituminous mixing plants and other road-making appliances Issued by Barber Asphalt Paving Co., Buffalo, N.Y.

Low Voltage Lighting Outfits.—A comprehensive bulletin describing the simplicity, adaptability, and convenience of low voltage lighting outfits for minor lighting purposes. Issued by the Northern Electric Co., Limited, Montreal.

The Lighting of Wood-Working Plants by Modern Methods.—A 12-page bulletin, describing and illustrating the possibilities of Mazda lamps for wood-working establishments. Issued by the Canadian General Electric Co., Limited, Toronto.

Motor-Driven Pumps.—A 24-page illustrated catalogue describing the advantages of the motor drive for pumps, the application of motors to pumps, and various pumping data, issued by the Westinghouse Electrical and Manufacturing Co., East Pittsburg, Pa.

Morris Trolleys.—Illustrated bulletin issued by the Herbert Morris Crane and Hoist Co., Limited, Toronto, dealing with the various types of travelling trolleys made by that company. Illustrations, diagrams and tables of dimensions are arranged in handy form.

Giant Cranes.—An elaborate 116-page catalogue issued by the Deutsche Maschinenfabrik, A.G., Duisburg, Germany, describing their stationary, travelling, slewing and floating cranes. This catalogue is profusely illustrated with fine halftones of cranes in operation.

The Lighting of Machine Shops and Metal-Working Plants.—Illustrated bulletin No. 43,402 describing the importance of perfect lighting, the method of lighting and the superiority of Edison Mazda lamps for such lighting. Issued by Canadian General Electric Co., Limited, Toronto.

Forging Ahead in Business.—An interesting 88-page catalogue published by the Alexander Hamilton Institute, of New York. This catalogue is descriptive of their modern business course and service, and gives a brief biological sketch of each of the Advisory Council and staff and of the special lecturers.

Tarvia, The Modern Binder, Road Preserver, and Dust Preventative.—A finely-illustrated 48-page catalogue issued by the Barrett Manufacturing Co., New York, describing the preparation and application of their tar dust layers and tar binders. The illustrations are of fine roadways, streets and drives treated with or constructed from Tarvia.

Avery Automatic Scales.—20 pp. of illustrated and descriptive information of this type of automatic scales for coal and water in power plant installations and of totalizers, crane scales of various types for industrial service, issued by the Avery Scale Company, for whom Canadian Allis-Chalmers, Limited, Toronto, are Canadian agents.

Railway Sign Apparatus:—A 24 pp. catalogue descriptive of model 2-A signal of the General Railway Signal Co., Rochester, N.Y. Also a 64 pp. pamphlet descriptive of the same in a very convenient size containing numerous circuit diagrams, instructions for installation and maintenance, etc. The company have also issued a 12 pp. bulletin descriptive of their plate rail clips and detector bars; also an 8 pp. description of their improved lightning arrester.

United States Steed Products Company.—General catalogue 1914, third edition, dealing completely with their many products, including rails, cross ties, switches, bonds, billets, blooms, etc.; also structural steel for buildings, bridges, derricks, etc. The catalogue comprises 635 pages, and covers almost every conceivable product, such as horse shoes, wire springs, tacks, nails, spikes, cables, ropes, fence wire, reinforcing mesh, music wire, etc.; conversion tables of weights, measures, specifications for structural work, steel railway bridges, steel axes, etc., etc.

Demag Cold-Rolling Machinery.—A handsome, finely-illustrated catalogue issued by Deutsche Maschinenfabrik A.G., Duisburg, Germany, describing their cold-rolling machines for the manufacture of long bands of steel, brass, iron, copper, tin, zinc, etc. Other types of rolling mills, circular and roll shears, straightening machines and other auxiliary equipment for rolling mills are described and illustrated. This catalogue, containing 48 pages, is representative of a high-grade manufacturing plant.

AREA OF THE PROVINCE OF ONTARIO.

On page 739 of our issue of May 14th, the division, by the Public Roads and Highways Commission of the Province of Ontario, as set forth in their recent report, does not include the addition of the district of Patricia in 1912. Two hundred and sixty thousand square miles represented the approximate area prior to this addition. The total area of the Province is now four hundred and seven thousand two hundred and sixty-two square miles, according to published statistics of the Department of the Interior, Ottawa.

Coast to Coast

Clinton, Ont.—Hydro-electric power was officially turned on at Clinton on May 20.

Hamilton, Ont.—$400,000 is being expended on extensions to the street railway system at Hamilton this year.

Neepawa, Man.—Recently, the waterworks dam has broken at Neepawa, Man., at a loss to the town of $3,000.

Toronto, Ont.—A report of statistics issued recently by the city waterworks department shows a deficit for 1913 of $141,371.

Baxter, Ont.—The centre span of the new viaduct over the Nottawasaga River at Baxter, sank recently, and will require to be repaired.

Moose Jaw, Sask.—The cost of the street paving, for which the city of Moose Jaw is now calling tenders, is placed at between $50,000 and $6[illegible].

St. Boniface, Man.—The Western Tire and Rubber Co., will locate its new factory, which will cost $175,000, at St. Boniface, rather than at Regina, as previously intended.

Regina, Sask.—Without taking into consideration the cost of labor, Regina will spend $28,075 in extensions to the electric light distribution system during the present year.

Calgary, Alta.—It is reported that lack of funds will cause the Grand Trunk Pacific Railway Company to delay starting the work of constructing its $300,000 station at Calgary.

Guelph, Ont.—Grading has been completed from Toronto to Guelph on the Toronto Suburban Railway line, and for the greater part of the distance ties have been distributed and rails unloaded.

Preston, Ont.—A proposition from the Building Product Co., manufacturers of sand bricks and other building material, offering to establish at Preston a $50,000 plant, is being considered by the municipal council.

Montreal, Que.—It is reported that 170 tenders were received at Montreal for 1914 street paving, and deposit cheques to the amount of $2,250,000 were received. The city will expend this year on pavement about $1,500,000.

Leaside, Ont.—The work on waterworks and sewage plants and systems, for which contracts have just been let, will entail an expenditure of around $100,000, which will be supplemented by the expenditure of $50,000 on roadways, pavements and other general improvements.

Quebec, Que.—The new 40-inch water pipe being laid in Quebec is almost completed. The whole of the lower portion of the city is already being supplied with water from this new main, and connection is being completed in the upper part of the city, while tests are being made.

Regina, Sask.—An effort is being made by the business men of Regina to have the Dominion Government extend its telegraph line from Qu'Appelle to Regina. It would be necessary to extend the existing line 70 miles to connect it with Regina, and the cost per mile would be approximately $1[illegible].

Winnipeg, Man.—The sum of $371,000 is being advanced to the city council by the sinking fund trustees for concrete lanes, street openings, granolithic sidewalks and No. 2 asphalt pavements for residential districts. This is in addition to $125,000 already loaned this year to the council, and [illegible] total $4[illegible].

Brantford, Ont.—The civic authorities and the Dominion Railway Commission have approved the general plans of the Lake Erie and Northern Railway Company for the raising of [illegible] and for the construction of the inner retaining wall of the railway, and it is expected that this work will commence at once.

St. John, N.B.—Mr. A. R. Gould, contractor for the railway being constructed down the St. John River valley from Woodstock, N.B., to the city of St. John, known as the St. John Valley Railway, when in Montreal recently, stated that the line between Gagetown and Centreville will be finished this year, and the track will be laid.

Montreal, Que.—Objections have been raised to the city conduit plant and construction work, and these must be considered by the Electric Service and Public Utilities commissions before final approval can be given for proceeding with the work. The chief objection to the St. Catharine Street conduit is that it was not provided for ventilation.

Winnipeg, Man.—After deducting the total operating expenses of $41,252.09 from the total revenue, the balance sheet of the city of Winnipeg hydro-electric system shows a surplus of $10,666.77 for the month of March. The deficit, which was incurred during the early months of the system's operation is gradually being reduced and this month stands at $86,156.60.

Sault Ste. Marie, Ont.—The amount which the city of Sault Ste. Marie will pay the Tagona Water and Light Co. for the water and light system on October 14 next, when their franchise expires, has been fixed by the arbitrators at $413,537.51. To this is to be added the statutory 10 per cent., which brings the total up to $454,891.26. The Tagona Water and Light Co.'s original figure amounted to $724,561.05.

Galt, Ont.—In his report on the waterworks system of Galt, Norman L. Wilson, the inspector for the Fire Underwriters' Association, pointed out an inadequate reservoir supply, and an inadequate source of water, artesian wells, showing evidence of diminishing the flow therefrom. He urged immediate steps to enlarge the visible supply reservoir to 3,000,000 gallons. The water commission has been considering means to increase the water supply for some time.

Yorkton, Sask.—The Yorkton board of trade sent a delegation recently to Winnipeg to endeavor to induce the C.N.R. to hasten the construction of its Yorkton branch, which is at present completed to within 18 miles east of the town and graded as far as 20 miles west. The delegation was also commissioned to ask both the C.P.R. to extend its yards and to make improvements generally, and the G.T.P. to continue its train service which was in operation a year ago. It is stated that the last request has practically been granted.

Vancouver, B.C.—It is expected that by June 1, a portion of the wharf of the new dock which is being established on the south side of False Creek near the Great Northern bridge at Vancouver, by Messrs. McNeill, Welsh and Wilson, Limited, will be completed. The wharf is 308 feet long and 176 feet wide, and will be approached by a roadway from the present end of Front and Ontario Streets. A large tract of foreshore between the railway bridge and the dock is to be reclaimed in connection with the dockage scheme, and will be used for trackage facilities.

Chatham, Ont.—The Chatham Gas and Electric Light Company has renewed its offer to sell its plant to the city for $410,000, plus the amount spent on capital account since the valuation of the plant made by the Hydro-Electric Commission. It is the intention of the city to use the plant of the gas company as a distributing station for Niagara power and to operate the gas end of the business as a public utility. The Hydro-Electric Commission recommended this deal to the city as the best business proposition when the city installed hydro-power. The council will give a decision within two weeks.

Winnipeg, Man.—What is stated to be a record piece of railway construction work has been accomplished by the

C.P.R. in the building of its Bassano-Swift Current line. This line is now complete from Bassano to Saskatchewan River, a distance of 125 miles. Track laying was started on March 1 last and was completed on May 15. In the last three days 12 miles of track were laid, 6 of these being done on the last day. The rails used are 85 pounds, and in the construction of the line, 2,900 ties to the mile were used. There are also 15 miles of passing and side tracks in the 125 miles completed.

Calgary, Alta.—No remaining doubt is now held concerning the commercial value of the oil which has been struck at the well of the Calgary Petroleum Produce Company near Black Diamond, and about 40 miles south-west of Calgary. The latest reports show that the fluid is almost pure gasoline, and that there were 500 feet of oil in the well, when it had reached a depth of 2,718 feet. Moreover, it is reported that on May 20, oil spouted from the Dingman well fully 90 feet into the air, and that after baling for more than four hours, there was no perceptible decrease in the height of the oil in the pipe, which remained at 2,000 feet. It is now estimated that within the next 60 days, drilling on about 100 wells will be commenced.

Victoria, B.C.—The decision has been announced from Ottawa that the new Government telescope, which is to be the largest in the world, and which is to cost $90,000, will be erected at Victoria, B.C. The instrument will be placed at the summit of Little Saanich Mountain, 7 miles from Victoria. Atmospheric conditions at Victoria have been found to be almost ideal for observation purposes. Tests at various places throughout Canada were made, but the decision was in favor of Vancouver Island. The new telescope has a reflecting lens of 72 inches and is 30 feet long. It weighs 8 tons, while the moving apparatus weighs 40 tons. The telescope costs $90,000 and the cost of the whole plant will be $200,000. The telescope and observatory were designed by Dr. Plaskett, of the Observatory Staff at Ottawa.

Regina, Sask.—In August a new 3,000 k.w. electric light unit will arrive at Regina to be installed at the new power house, and will give sufficient equipment in the two power houses to handle double the city's load, and to ward off inconvenience to consumers in case of a breakdown. The new machine will have twice the capacity of any of the units at present installed; though in appearance it will not be very much larger than the 1,500 k.w. units. The consumption of electric energy is increasing very rapidly, and at the present rate of increase the new machine will be needed for constant use soon after it is installed. Wilson and Wilson, who were awarded the contract for the completion of the new power house, are assembling machines on the ground, and it is expected that actual construction work will be under way this week.

Vancouver, B.C.—As proposed by H. J. Kaiser, a contractor on one of the city's paving works, a new pavement, which may take the place of macadam on Vancouver's streets, will be laid on a section of Fourteenth Avenue. It is a bituminous mixture 5 inches in thickness made up of sand and gravel, bound together with bitumen. There is no concrete base, but the mixture is laid on the surface of the ground and rolled smooth. It will cost $1.35 a square yard as compared with 90 cents to $1 for macadam. The pavement will be guaranteed for five years, and it is believed may last twice that time; and it is declared that the extra cost will be more than saved in the lower expense of maintenance. It is stated that this pavement has been used extensively in United States cities.

Victoria, B.C.—The Burrard Engineering Company, of Vancouver, to which has been let the contract for the fabrication and laying of the pipe in connection with the Sooke Lake waterworks system, has [illegible] the [illegible] Westholme Lumber Company at Thetis Cove, Esquimalt Harbor, and will use this for the fabrication of the pipe. The company expects to be in a position to deliver pipe in about two or three weeks; and, so that no delay may be encountered when the pipe is ready, within the next week or 10 days the city will commence work on the excavation of the 10-mile trench in which the steel pressure pipe will be laid from Humpback Reservoir to the city. With the commencement of the laying of the reinforced concrete pipe along the section from Sooke Lake to Cooper's Cove, and a start on the laying of the steel pipe line from the reservoir to the city, the operations on the waterworks system for Greater Victoria will enter its final stage. The city will soon complete its work and there will be nothing in the way of the pipe line contractors pushing ahead their part of the contract.

Vancouver, B.C.—Tracklaying has been commenced on the extension of the P.G.E. Railway from Dundarave to Horseshoe Bay, and it is expected to have the line completed to the Howe Sound end early in June. The section is to be ready for operation by July 1. The railway company, in order to expedite operation on the Dundarave-Horseshoe Bay portion of the route, is building bridges in advance of the tracklayers. This involves greater expense in transporting materials; for timbers and steel have to be floated on rafts to the different bridge sites. Additional orders have just been placed by the P.G.E. for gasoline locomotives and rails. Two heavy engines of the consolidated type have been purchased from the Canadian Locomotive Works of Kingston, Ont., and three large passenger coaches have been bought. The company already had previous to these orders two locomotives on order and four in service. Sufficient steel to lay more than 300 miles of track has been ordered from the Algoma Steel Co. of Sault Ste. Marie, for delivery during the present year and up to the end of 1915. These consignments will aggregate between 30,000 and 40,000 tons. Contractors are now preparing to start active construction operations on the sections south of Fort George and north of Clinton; and a number of subcontracts are expected to be let at an early date for other portions of the line.

Regina, Sask.—In addition to many large buildings to be erected at Regina, the city has this year entered upon a programme of local improvement work which will require an expenditure of $2,033,264.03. The works and the expenditures estimated are as follows: waterworks general, $360,000; water main extension, $127,752; domestic sewer extensions, $142,145.23; storm sewers, $170,000; sewage disposal works, $61,520; street railway extensions, $250,000; pavement, $452,946.80; sidewalks, $65,000; and electric light and power, $404,000. Some of the many large buildings which at present are either under construction or are proposed to be erected at Regina, are given as follows, together with their estimated costs: G.T.P. Railway hotel, $1,000,000; G.T.P. station, laundry, train sheds, power house and tunnel, $1,000,000; Methodist College, towers and residence, $125,000; Rose theatre, $50,000; two business blocks, $75,000; Dominion Government buildings, $225,000; Campbell, Wilson and Strathdee warehouse, $112,000; General Hospital addition, $75,000; police station, $180,000; power house, $450,000; Woolworth's stores, $50,000; Nurses' Home, between $80,000 and $90,000; Metal, Shingle and Stamping Co.'s building, $[illegible]; [illegible] Lake Milling Co.'s mill, $300,000; Regina incinerator (now completed), $65,000; Presbyterian College, $1,000,000; Merrill and Garbutt [illegible], $[illegible], and [illegible], $[illegible]. It is stated [illegible] that the Roman Catholic Church will [illegible] a college at Regina, and that construction will likely commence this year. Moreover, many large apartment blocks, and other buildings to cost less than $50,000, will be erected this year in this city.

PERSONAL.

C. E. FOWLER, C.E., of Seattle, who is the author of the article entitled "Important Principles of Bridge Design," in this issue, on May 15th, delivered an illustrated lecture before the Vancouver branch of the Canadian Society of Civil Engineers on the harbors of the world.

H. D. MAPLES has been appointed superintendent of building construction for the C.P.R. in succession to F. L. Ellingwood. For a number of years Mr. Maples was vice-president of J. V. Schafer, Jr., and Company, a contracting firm of New York. He entered the service of the C.P.R. two years ago as assistant to Mr. Ellingwood. Mr. Maples has had 22 years' experience as an engineering contractor.

Recent appointments to the staff of the Topographical Surveys branch, Department of the Interior, Ottawa, includes, Messrs. E. A. Hodgson, Toronto; R. H. Field, Fort William; D. H. Campbell, Rodney, Ont.; H. C. Johnson, Ottawa; C. C. Fitzgerald, Parry Sound; G. L. Wallace, Toronto, and J. H. Hawes, Toronto.

OBITUARY.

The death occurred last week of Mr. A. C. Morris, secretary-treasurer of the Ontario Wind Engine and Pump Co. Mr. Morris came to Canada 27 years ago at the age of 23. He became connected with the Brockville Motor Co., but afterwards came to Toronto, and has been in the employ of the Ontario Wind Engine and Pump Co. since.

We regret to record the death of Alex. K. Kirkpatrick, C.E., of Queen's University, Kingston. Professor Kirkpatrick was prominently known among Canadian Civil Engineers. His connection with the Canadian Pacific Railway on several of its important projects, and his latest work, viz., the design of the Government car ferry service between Prince Edward Island and Cape Tormentine, N.B., have been well worthy of professional approval, and are an indication of his ability. Prof. Kirkpatrick was at the head of the Department of Civil Engineering at Queen's University. He was a member of the Canadian Society of Civil Engineers. At the time of his sudden death he was at Cape Tormentine in connection with the construction of the car ferry.

DESIGN OF THE OSHAWA POWER PLANT.

In the issue of May 21st, we overlooked mentioning, in connection with the article entitled "Oshawa Sub-Station of the Electric Power Co.," that the plant was designed by the engineering firm of Smith, Kerry and Chace, Limited, Toronto.

OFFICERS OF ELECTRIC RAILWAY ASSOCIATION.

At a recent convention, in Ottawa, of the Canadian Electric Railway Association, the following officers were elected:—President, C. B. King, manager, London Street Railway; vice-president, J. D. Fraser, secretary-treasurer and director Ottawa Street Railway; secretary-treasurer, Acton Burrows, Canadian Railway and Marine World, Toronto; executive committee—E. P. Coleman, general manager Dominion Power and Transmission Co., Hamilton; A. Eastman, vice-president and general manager Windsor, Essex and Lake Shore Rapid Ry., Kingsville; A. M. Hopper, general manager St. John, N.B., Street Ry.; Wilson Phillips, superintendent Winnipeg Electric Ry.; C. L. Wilson, assistant manager Toronto, York Radial Ry.; Patrick Dubee, secretary-treasurer Montreal Tramways Co.

REORGANIZATION OF WINNIPEG ENGINEERING DEPARTMENT.

At the resignation of Col. H. N. Ruttan, after 29 years of service as city engineer of Winnipeg, a reorganization of the city engineering department was decided upon by the board of control and the city council. As stated in a recent issue of this journal, Col. Ruttan is being retained as consulting engineer, and W. P. Brereton, B.A.Sc., chief assistant engineer, has been appointed to fill the vacancy on the engineering staff.

Whereas in the past, Col. Ruttan has been head of the entire department, and responsible for all matters pertaining to its branches, the new policy divides the department into sections with recognized heads over each, directly responsible to the board of control, although the new city engineer will be vested with the same authority as in the past. Thus Mr. Brereton, in his new position, will have general supervision. Mr. Wm. Aldridge, who has been in the city service for 14 years, is to have charge of office work, designing and detail specifications. Mr. Byde Hallock, who has also been in the city's employ for many years, having been in charge of outside construction work, is to be field engineer, thus continuing for the most part, the work upon which he has been engaged, including pavements, sewers, water mains, sidewalks, etc, The operation of the waterworks department will be under Mr. Thos. H. Hooper. This sub-department will not include construction, but only operation of the whole system, including the wells outside the city limits. Mr. Paul Schioler will be in charge of bridge construction and maintenance. He has been bridge engineer to the city for the past five years.

COMING MEETINGS.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30th to July 4th, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—Summer convention to be held at Brighton Beach, N.Y., July 3rd and 4th, 1914. Secretary, J. R. Wemlinger, 11 Broadway, New York.

UNION OF CANADIAN MUNICIPALITIES.—Annual Convention to be held in Sherbrooke, Que., August 3rd, 4th and 5th, 1914. Hon. Secretary, W. D. Lighthall, Westmount, Que. Assistant-Secretary, G. S. Wilson, 402 Coristine Building, Montreal.

AMERICAN PEAT SOCIETY.—Eighth Annual Meeting will be held in Duluth, Minn., on August 20th, 21st and 22nd, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

CANADIAN FORESTRY ASSOCIATION.—Annual Convention to be held in Halifax, N.S., September 1st to 4th, 1914. Secretary, James Lawler, Journal Building, Ottawa.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal.

CONVENTION OF THE AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—To be held in Boston, Mass., on October 6th, 7th, 8th and 9th, 1914. C. C. Brown, Indianapolis, Ind., Secretary.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9th to 13th, 1914. I. S. Pennybacker, Executive Secretary, and Chas. P. Light, Business Manager, Colorado Building, Washington, D.C.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21749—April 27—Authorizing Cedars Rapids Mfg. and Power Co., of Montreal to take additional width of 24.8 ft. for right of way for its transmission line across East Half Lot 31, Con. 1, Tp. Lancaster, Co. Glengarry, Ont., property of D. Ross Ross, subject to and upon certain conditions.

21750—May 1—Appointing P. H. Drayton, Esq., K.C., as arbitrator to inquire into and determine what, if any, damages have been sustained by Heward Estate, in connection with construction of C.P.R. spur (Government Spur Line) in city of Toronto, Ont., and to fix compensation therefor.

21751—April 29—Directing that C.P.R., and O. and N.Y. Ry. Cos., on or before June 1st, 1914, schedule trains No. 30 and 305 (C.P.R.) and No. 20 (O. and N.Y.) at Finch, Ont., at 9.52 a.m., and to carry out certain directions in connection wih said trains; and rescinding Order No. 19265, dated May 13th, 1913.

21752—May 2—Approving and authorizing clearances as shown on C.P.R. plan showing clearances on Rogers Pass Tunnel, subject to condition that Ry. Co. keep its employees off top and sides of cars operated through said tunnel.

21753—May 2—Relieving G.T.R. from providing further protection at crossing of highway first west of Stoney Creek, Ont.

21754—May 4—Approving revised location G.T.P. Branch Lines Co., Moose Jaw Northwest Branch from North Boundary of Sec. 19-22-7, to East Boundary of Sec. 25-22-8, W. 3 M., mileage 73.34 to 77.98, Dist. Moose Jaw, Saskatchewan.

21755—May 4—Authorizing C.P.R. to construct bridge No. 18.1 on Moose Jaw Subdivision, Sask. Division, Saskatchewan.

21756—May 4—Authorizing C.P.R. to construct diversion of Old Trail to Medicine Hat, in Sec. 36-22-29, W. 3 M., Sask.; and construct, at grade, track of its Swift Current Northwesterly Branch Line across said diversion.

21757—May 4—Directing that, within 90 days from date of this Order, C.P.R., install improved type of automatic bell at crossing of first public highway east of Central Ontario Junction, and thereafter maintain bell at own expense; 20 per cent. of installation of bell be paid out of "The Ry. Grade Crossing Fund," remainder by Railway Company.

21758—May 6—Approving revised location portion of C.P.R., Swift Current Northwesterly Branch Line, from point in Sec. 14-36-11, W. 4 M., mileage 0, in northwesterly direction to point in Sec. 6-38-11, W. 4 M., mileage 10.82 of said Branch Line (mileage 0-105.60 Lacombe Subdivision).

21759—May 5—Authorizing C.P.R. to construct tracks of storage siding, at grade, across public road between city of Guelph and Tp. Guelph, Co. Wellington, Ont., at mileage 30.33, Ont. Div. Hamilton and Goderich Subdivision.

21760—May 6—Authorizing, subject to conditions contained in Order in Council, Dominion Atlantic Ry. to reconstruct bridge over Bear River, Co. Digby, N.S., and approving plan No. B-1-1261, marked plan "A," showing location of proposed temporary lift span in old bridge.

21761—May 5—Authorizing C.P.R. to construct spur for Builders Supply Co., Limited, Winnipeg, Man., in Sec. 36-11-4 E.P.M., on lands owned by Builders Supply Co., Limited.

21762—May 5—Authorizing C.P.R. to take certain lands in city of Ottawa, Ont., for purpose of enlarging Sussex St., terminals in said city of Ottawa.

21763—May 6—Authorizing C.P.R. to construct change in location of spur for Security Lumber Co., Limited, Moose Jaw, Sask., from point on existing spur in Subdivision Lot 35, thence across Subdivision Lots 35 to 22, both inclusive, Block 98, city of Moose Jaw, Sask.

21764—May 6—Approving location and details of C.N.Q. Ry. station at Lac aux Sables, Quebec.

21802—May 13—Approving Bell Telephone Co.'s agreement entered with Pontiac Rural Telephone Co., Limited, dated April 3rd, 1914, for interchange of telephone messages or service passing to or from their respective telephone systems, division or apportionment of tolls, and management, working, or operation of respective telephone systems, etc.

21803—May 14—Approving location C.P.R. station at Ringold, Lot 8, Con. 3, Tp. Raleigh, Co. Kent, Ont., mileage 70.99, Windsor Subdivision: Provided, whenever highway is blocked for more than 5 minutes at any one time by reason of location hereby approved, Board shall be at liberty to re-locate said station.

21804—May 14—Authorizing C.P.R. to construct spur for George White & Sons, Co., Limited, city of Moose Jaw, Saskatchewan.

21805—May 14—Authorizing C.P.R. to construct spur for Mond Nickle Co., Limited, Coniston, Ont., in Lots 5, 6, and 7, Con. 6, Tp. of McKim, Dist. Sudbury, Ont., mileage 2.5 on Stobie Branch.

21806—May 14—Authorizing C.P.R. to construct spur for Thomas Fletcher, of Calgary, Alta.

21807—May 14—Relieving C.N.R. from speed limitation of 18 miles an hour over its line from Oak Point to Gypsumville, a distance of 97 miles; and directing that fencing of its line from mileage 69 be erected and completed by Oct. 1st, 1914.

21808—May 15—Authorizing C.N.O.R. to construct bridge to carry its line over Raimbault Creek, parish St. Laurent, Co. Jacques Cartier, Que., mileage 48.07 from Hawkesbury; and rescinding Orders Nos. 19657 and 21650, dated respectively June 21st, 1913, and April 15th, 1914.

21809—May 11—Approving G. T. P. Ry. plans showing stress diagram of superstructure and details of substructure of bridge across Nechaco River, mileage 371.4 Prince Rupert Easterly, B.C.

21810—May 16—Amending Order No. 20002, dated August 11th, 1913. 1. by substituting plan dated April 24th, 1914, for plan approved under Order No. 20002, and 2. by adding to last line of operative part of Order following words,—"and the Applicant Co. is hereby authorized, at its own expense, to raise the tracks of the C.P.R. Co., six feet at the point of crossing."

21811—May 11—Directing that classification of maple cheese be made same as that fixed by Order No. 21745, dated May 2nd, 1914, for maple butter; addition to be included in Supplement No. 3 to Canadian Freight Classification No. 16.

21812—May 16—Authorizing C.N.R. to reconstruct bridge over Sturgeon River, station 403, mileage 8.1, River Lots 53 and 25, St. Albert Settlement, Alberta.

21813—May 14—Authorizing C.N.O.R. to construct bridge over Indian River, Tp. Richards, Co. Renfrew, Ont., mileage 107.85 from Ottawa; and rescinding Order No. 120888, dated November 21st, 1913.

21814—May 16—Authorizing C.P.R. to open for traffic its line from mileage 0 to 10, Snowflake West Branch, Manitoba.

21815—May 13—Directing that, within 60 days from date of this Order, C.P.R. install automatic bell at crossing of Laviolette Avenue Three Rivers, Que., 20 per cent. of installation to be paid out of "Ry. Grade-Crossing Fund," remainder by Railway Company.

21816—May 14—Authorizing C.P.R. to construct spurs from point on north-easterly limit of right of way of main line, mileage 2.26, Muskoka Subdivision, Ont. Div., in Lot 1, Con. 4, west of Yonge St., Tp. York, Ont., on land owned by Canadian Kodak Co., Ltd.

21817—May 14—Authorizing G.T.R. to construct siding into premises of Brantford Industrial Realty Co., Ltd., south of Alice Street, city of Brantford, Ont.

21818—May 16—Approving and authorizing clearances as shown on C.P.R. plan showing clearances of overhead pipe line crossing sidings of Standard Paint Co. of Canada, Ltd., in Lot Cadastral No. 954, parish Lachine, Co. Jacques-Cartier, Que., at mileage 0.49, on South Bank Branch, subject to condition that Co. keep employees off top and sides of cars operated over said siding.

21819—May 11—Authorizing Hamilton Radial Electric Ry. Co., to construct spur, Tp. Saltfleet and Tp. Barton, Co. Wentworth, Ont. to and through lands of Sir Henry Pellatt and Dominion Power and Transmission Co., Ltd., at or near point marked "B," subject to certain conditions.

21820—May 11—Authorizing C.P.R. to construct extension to trackage for Gordon, Ironside and Fares Co., Ltd., Winnipeg, Man., and approving all clearances as shown on plan dated Winnipeg, April, 1914, subject to condition that Company keep employees off sides of cars when operated over said spur.

21821—May 11—Directing that C.P.R. construct roadway 66 ft. wide, commencing from north and south road allowance and running north-westerly to point south of dam, and thence north-westerly joining east and west road allowance in centre of Sec. 17 and 8; and reserving question of apportionment of cost.

21822—May 18—Approving revised location G.T.P. Ry. main line mile 220.60 to mile 230.30, Yellowhead Pass West, Dist. of Cariboo, B.C.

21823—May 18—Authorizing G.T.P. Ry. to operate crossing of Canadian Northern at Empire Ave., Fort William, without bringing trains to a stop.

21824—May 18—Authorizing G.T.R. to re-construct overhead bridge carrying farm crossing over tracks Lot 33, Con. 1, Tp. of South Dumfries.

21825—May 14—Amending Order No. 138, dated June 17th, 1904, which authorizes crossing by Sarnia Street Railway of G.T.R. (Point Edward Blackwell Branch) by adding clause that the Applicant Co., bear and pay the cost of maintaining and repairing the diamond.

21826—May 18—Authorizing C.P.R., to use and operate Bridge No. 144.6 on its Portal Subdivision, Saskatchewan Div.

21827—May 18—Extending until June 30th, 1914, the time for completion of siding for McCormick Mfg. Co., London, Ont., authorized by Order No. 20710, dated November 4th, 1913.

21828—May 11—Rescinding Order No. 21518, dated March 18th, 1914, which directed the C.P.R., to restore the old clearance at the bridge over North Branch of Clyde River, just north of Flower Station, Ont., by raising under side of top of culvert eleven inches.

21829—May 18—Extending until November 1st, 1914, the time for construction and completion of subway under C.P.R., in Regina, authorized by Order No. 12801, dated January 20th, 1911, on application of city of Regina.

21830—May 19—Authorizing Board of Highway Commissioners, Sask. to construct highway crossing over C.P.R., in S.W. ¼ Sec. 21, Tp. 19, R. 18, W. 3 M., Sask.

21831—May 16—Authorizing Cedar Rapids Manufacturing and Power Co. to take certain lands in Lots 3, 4 5, parish of St. Ignace du Coteau du Lac, properties of Mrs. O. S. Bissonnette.

21832—May 18—Authorizing town of Mont Laurier, Que., to construct highway crossing over C.P.R. at mile 134.45, Laurentian Subdivision, Tp. of Campbell, Labelle Co., Que.

21833—May 19—Authorizing C.N.R. to cross public road between Secs 14 and 15, Tp. 51, Rge. 12, W. 4 M.

21834—May 18—Authorizing C.N.Q. Ry. to construct spur to Dansereau's Mill, and to cross Bay St., Grenville, Que.

21835—May 18—Authorizing G.T.R. to construct spur from a point on the 16th Dist. of its railway on Ferguson Ave., Hamilton, to the Co.'s property west of Ferguson Ave.

21836—Directing the G.T.R. to change the grade of approaches to crossing [illegible] Durham and South Durham [illegible] Bergvine Crossing.

21837—May 18—Authorizing G.T.P.B.L. Co. to construct a bridge across South Saskatchewan River at mile 86.5 Young Prince Albert Branch, Saskatchewan.

21838—May 18—Directing that the C.P.R. within 60 days date of Order install electric bell at crossing in Mun. of Maple Ridge, Port Hammond, B.C.

21839—May 16—Approving change in location of C.P.R. station at Kreuzburg, Man.

21840—May 18—Approving plan showing subway proposed to be constructed at Anthony St., Strathcona, Edmonton, by the C.P.R.

21841—May 18—Approving C.P.R. plan showing clearances at its coaling plant at Aldersyde, Alta.

21842—May 19—Authorizing C.N.O.R. to construct crossing of Con. Road between Lot 10, Con. 5, and Lot 10, Con. 6, Tp. Nepean, Co. Carleton, Ont.; rescinding Order No. 17859, November 6th, 1912, in so far as it approved road diversion at said point; and rescinding Order No. 20110, dated August 18th, 1913.

21843—May 20—Authorizing Rural Mun. Colonsay No. 342, Sask., at its own expense, to construct highway crossing over G.T.P. Ry. Co.'s Prince Albert Branch in N.W. ¼ Sec. 28-34-27, W. 2 M., Sask.

21844—May 20—Authorizing C.P.R. to construct spurs for White Falls Lumber Co., Limited, Sudbury, Ont., from point on Northeasterly limit right of way of main line, Lake Superior Div., Algoma Subdivision, at Blind River, Lot 5, R. 1, Tp. Cobden, Ont.

21845—May 20—Authorizing G.T.R. to construct siding into premises of Messrs. Aitken and Sons, on Lots 60, 59, 58, 57, 56, 55 and 54 west of Dayfoot St., village of Beeton, Ont.

21846—May 19—Authorizing C.P.R. to construct temporary sidings for Dominion Bridge Co., Limited, Montreal, from point on main line right of way, across Cushing Road and Provincial Government lands in parish of Lancaster, Co. St. John, Province of N.B., mileage 1.92, St. John Subdivision, authority granted herein be effective for one year from date of this Order.

21847—May 19—Directing that C.L.O. and W. (C.P.R.) lay and maintain a 12-inch pipe under its embankment, in West ½ Lot 30, Con. 2, Tp. Pickering, Ont.; Frederick Roach of Cherrywood, Ont. (Applicant), to have right to lay water pipe through said 12-inch pipe for purpose of conveying water from spring to pasture.

21848—May 18—Refusing application of Bell Telephone Co., for leave to construct lines of telephone upon, along and across Concord St., Grey Ave. and Harvard Ave., city of Montreal; and granting leave to said Company to erect and maintain an overhead line on east side of Mountain St. said city, pending construction of permanent pavement on said street, when wires shall be placed underground.

21849—May 20—Amending Order No. 21734, dated May 2nd, 1914, by adding after word "Streets" in clause (2) of paragraph 1 of operative part of Order, the following: "the said wires forming part of the circuits which are dealt with under clause (1) of this Order."

21850—May 18—Directing that C.N.R. construct and maintain a dam on creek diversion near north boundary Sec. 16-31-15, W.4 M., Alta., the crest of dam to be 6 inches higher than top of pipe under railway embankment; work to be completed within one month from date of this Order; and rescinding Order No. 21139, dated December 31st, 1913.

21851—May 22—Authorizing C.P.R. to open for traffic its second main line track from Iberville Station, mileage 19.2, to mileage 20.02, St. Johns, Quebec.

21852—May 16—Approving location G.T.R. station at Penetanguishene, Ontario.

21853—May 22—Amending Order No. 10457, dated April 28th, 1910, by adding "that all moneys expended in acquisition of any property required for work, including lands required for diversion of Upper Lachine Road, and all moneys paid in satisfaction of damages and taxed costs resulting from work, or any part thereof, shall be considered as forming part of cost of work directed by this Order and shall be borne in the proportions above set out."

A report has been made to the effect that Vickers Maxim Company has secured control of the plant of the Collingwood Ship Building Company, and also the Kingston Ship Building Company, and that these works will be operated in conjunction with the navigation companies.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

CASCADE RIVER POWER DEVELOPMENT

DESCRIPTION OF THE PROPOSED HYDRO-ELECTRIC PLANT AT BANFF, ALTA., FOR THE DOMINION PARKS BRANCH, DEPARTMENT OF THE INTERIOR.

IN the following article, taken from a report of C. H. Mitchell, C.E., consulting engineer to the Water Power Branch, Department of the Interior, the feasibility and commercial economic development is considered of a hydro-electric power project capable of supplying power to be used by the Dominion Parks Branch

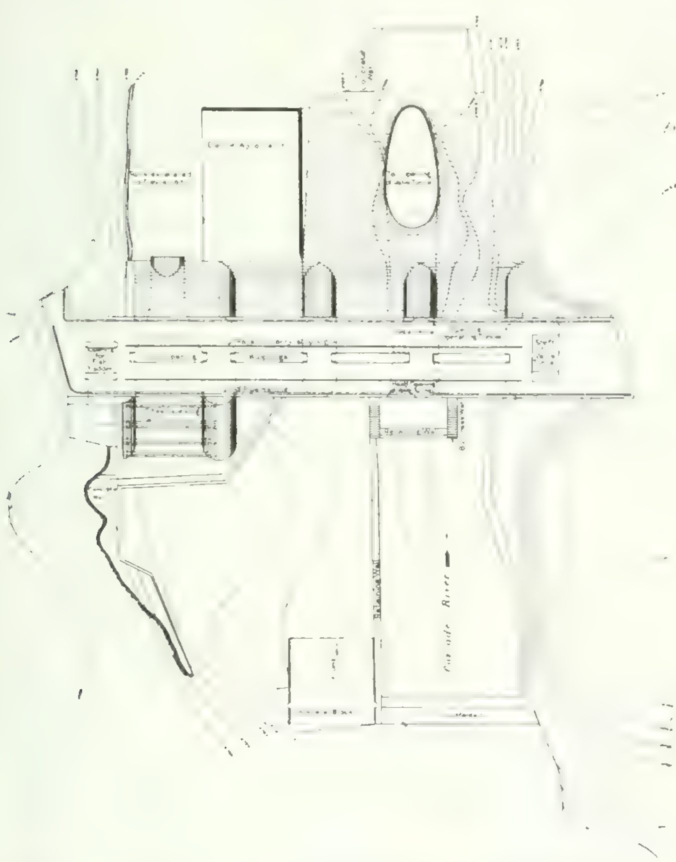

Fig. 1.—General Plan of Minnewanka Storage Dam of the Calgary Power Company.

to furnish the town of Banff, Alta., with light, transportation, etc., and to develop various electrical undertakings in the Rocky Mountains Park in the vicinity of Banff.

The Cascade River, where flowing through the canyon in which it is proposed to develop the power, is immediately below the confluence of Devil's Creek, which empties from Lake Minnewanka. The total area drained by these rivers is about 213 sq. mi., and lies wholly within the Rocky Mountains; much of the water originates in mountain lakes and some in glaciers. Lake Minnewanka has an area of about 14 sq. mi., and was, during 1912, converted into a storage reservoir for power purposes to improve the power facilities of the Bow River in its power-producing reaches in the foot-hills of the mountains.

The power site is about 7 miles from the town of Banff. The nearest railway point is at Bankhead coal mines, three miles from the site. The small town site, one mile above, on the shore of Lake Minnewanka, is likely to become almost entirely a summer place; the village of Bankhead has a mining population of permanent character serving the mines. The power site and all the other portions of the project lie wholly within the Rocky

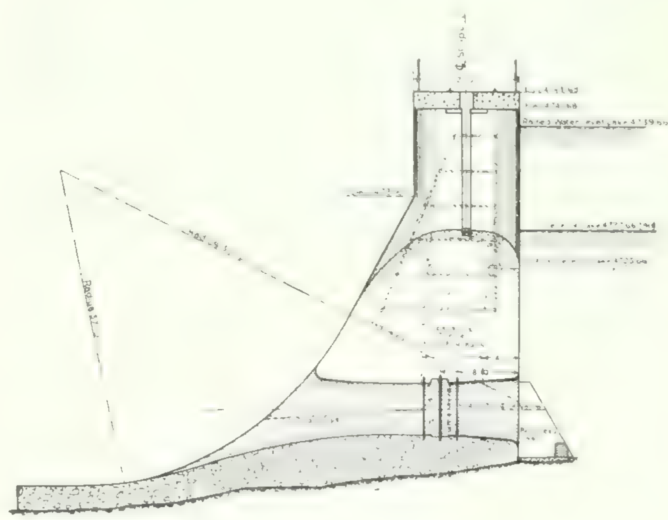

Fig. 2.—Section of Minnewanka Storage Dam.

Mountains Park and thus all water privileges, lands and rights of way are secured for the undertaking, the title being in the Crown through the Department of the Interior.

The natural water supply has been very much improved by regulating works which have been constructed just below the confluence of the Cascade River and Devil's Creek by the Calgary Power Company, Limited, under the supervision of the Department of the Interior. Primarily, these works are for increasing the water supply, especially in the winter months, to the Calgary Power Company's plants, one at Horseshoe Falls, and one more recently constructed, at Kananaskis Falls, on the Bow River, about 35 miles distant by river. It is contemplated, however, in the agreement entered into by the

Minister of the Interior and the Power Company, that this water so stored on Lake Minnewanka will be used jointly by the Calgary Power Company and the various other power users on the Bow River which may be established under future agreements with the department, the Minister having the right to control the operation of the dam.

As to the actual water supply available for power purposes, the department has taken advantage of the construction of the storage dam to secure therefrom a

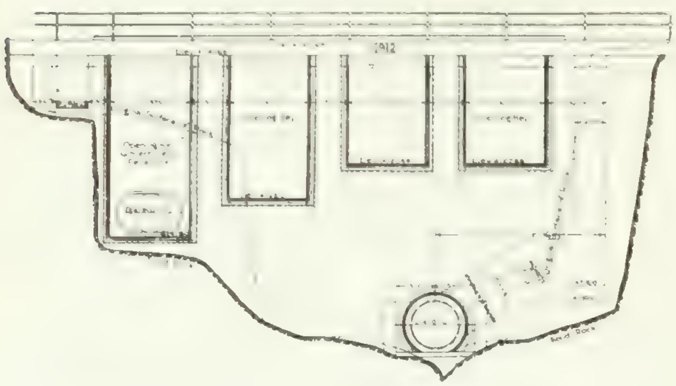

Fig. 3.—Upstream Elevation of Dam.

continuous supply of at least 150 cu. ft. per sec. throughout the year.

At those seasons of the year when the river is naturally in flood, the dam would be impounding water, but it is expected that the lake reservoir would be full to its allowable height, usually by July 15 at the latest; after that date there would be water wasted over the spillways of the dam, gradually diminishing in quantity to the end of the summer. Measurements over several years during July, August and September, indicate that at least 200 sec.-ft. can be obtained for power purposes, independently of the storage process. During the early summer this amount can readily be made available during the filling process. In the autumn months a natural supply of practically 200 cu. ft. per sec. can be depended upon, while in winter, when the storage is called upon to supply water for deficiencies, the available water under the agreement mentioned above can be increased from 150 to 200 sec.-ft. by increasing the height of the storage or lowering the level of the draw-off. Thus 200 sec.-ft. would be continuously available for 24-hour use, and the proposed works are designed for the possible use, during peak requirements for short periods under exceptional conditions, of 330 cu. ft. per sec.

Power Obtainable.—The storage dam now built has been arranged so as to provide a headworks dam and intake for securing the water for power purposes, and provides about half the total head of water contemplated in the development. The other half is in the natural fall of the river itself in the intervening distance between the dam and power station sites.

The nature of the dam, being primarily for storage, provides for the necessary fluctuation of Lake Minnewanka levels. This fluctuation, while varying the head available for power purposes, does not unfavorably affect the power to be obtained when considering the commercial side of the undertaking, because the low-water level, and consequently the low working head will occur in the winter and spring periods when the demand for power is less than at midsummer. On the other hand, when the demand will be at a maximum for this plant in the tourist season, say, during July and August, the storage basin will be filled to its maximum, and the head, and consequently the power, to be obtained will be at a maximum. As both the head obtainable and the amount of water available will both be at a maximum in July and August, when most needed, the obvious type and design is one which would have a capacity utilizing the maximum head and 200 cu. ft. of water per sec., with provision for over-development in capacity capable of using up to 330 cu. ft. per sec., as stated.

The gross head of the development with the storage basin filled to its highest level, is about 64 feet, of which

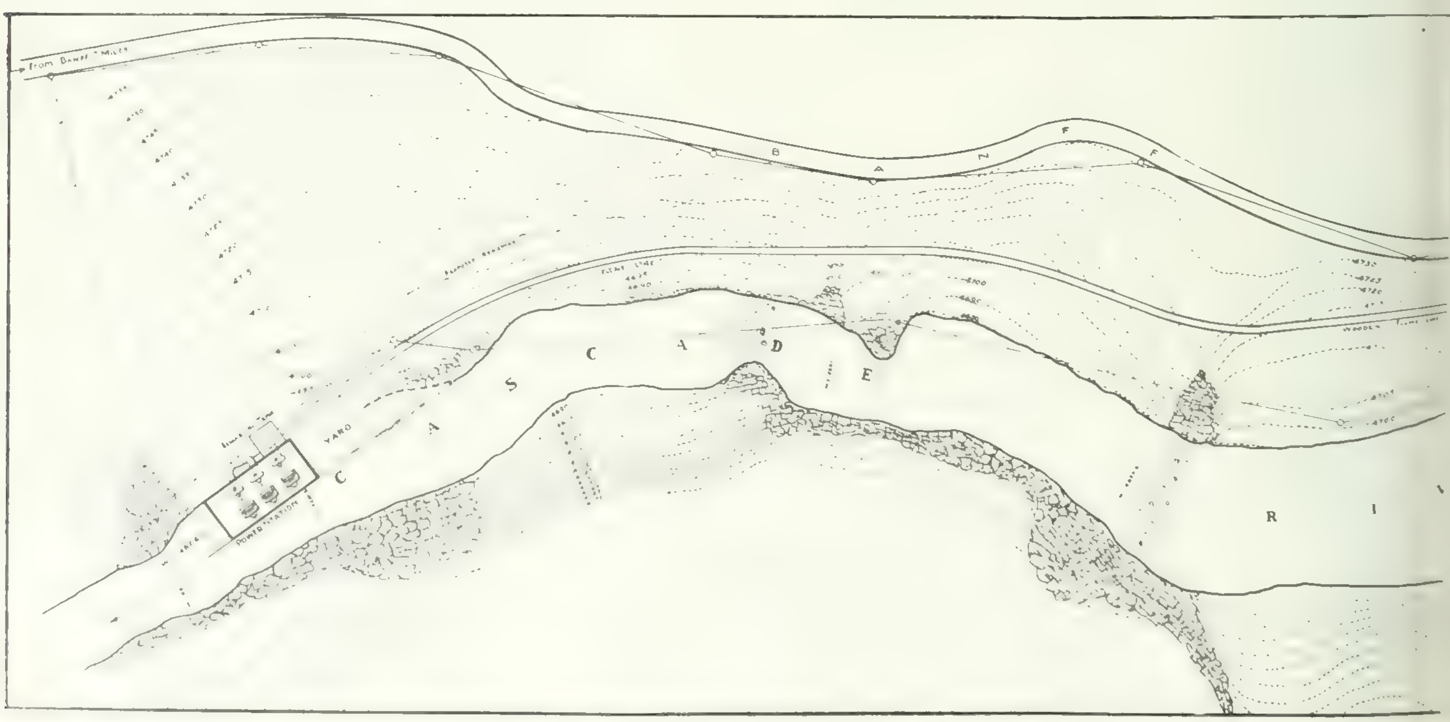

Fig. 4.—General Layout of Proposed

we compute 60 feet may be taken as the effective head on the turbines. Under these conditions, at least 1,800 h.p. can be obtained in electrical output at the power station as a maximum capacity such as might be required at "peak load" periods. This power, after transmission to Banff, will be reduced to about 1,500 h.p. net, ready for delivery to the consumers.

In order to secure this capacity of plant, it is proposed to at first construct all the general works, including the power station, to the full ultimate capacity. As, however, it is anticipated that this total amount of power will not be required in Banff in the early stages of the undertaking, it is proposed herein to place power equipment in the power station for only 2/3 of the above capacity—that is, to install only two of the three power units at present. The initial development will, therefore, provide about 1,000 h.p. in Banff.

Method of Development.—The head dam, already constructed, is at the head of the rocky canyon and is a solid concrete structure, having facilities for discharging water either over its crest through stop-log spillways or through a low level in a sluiceway closed by a gate valve. It is also provided with an intake, a stop-log opening and a forebay into which a steel penstock thimble, 5 ft. in diam., is inserted ready for connecting in the future to a penstock or flume to lead the water to the power station. This thimble has an up-stream size of 8 x 5 feet, to serve as an intake, and reduces to 5 feet in diameter, which will enable a species of Venturi water meter to be established for measuring the water used. The necessary works for the development of power commence, therefore, at the outer end of this thimble which is already in place. The intake and penstock are set at a sufficiently low level to accommodate any level of water between the limits in which the storage basin will fluctuate.

It is to be noted that with the drawing down of the water above the dam the head will be reduced, but this will occur at a season when the demand for power will not be great.

Penstock and Flume.—It is proposed to lead a 7-ft. steel pipe from the present thimble along the cliff a short distance and then enter a 7 x 8-ft. tunnel cut in the rock on the south side of the river, and emerging at the lower end of the canyon. It is not anticipated that this tunnel will need to be lined except in the bottom and sides to offer a smooth course for the water flow.

The penstock is proposed to span the canyon as a 7-ft. diam. steel pipe, supporting itself at a height about 15 ft. above the water. From this point it is proposed to carry the penstock down the north bank as a wooden stave flume of 7-ft. diam. under pressure, and set in a partial excavation. At one point this will require to be supported for about 150 ft. on concrete piers. At the lower end the flume would be buried beneath the station yard.

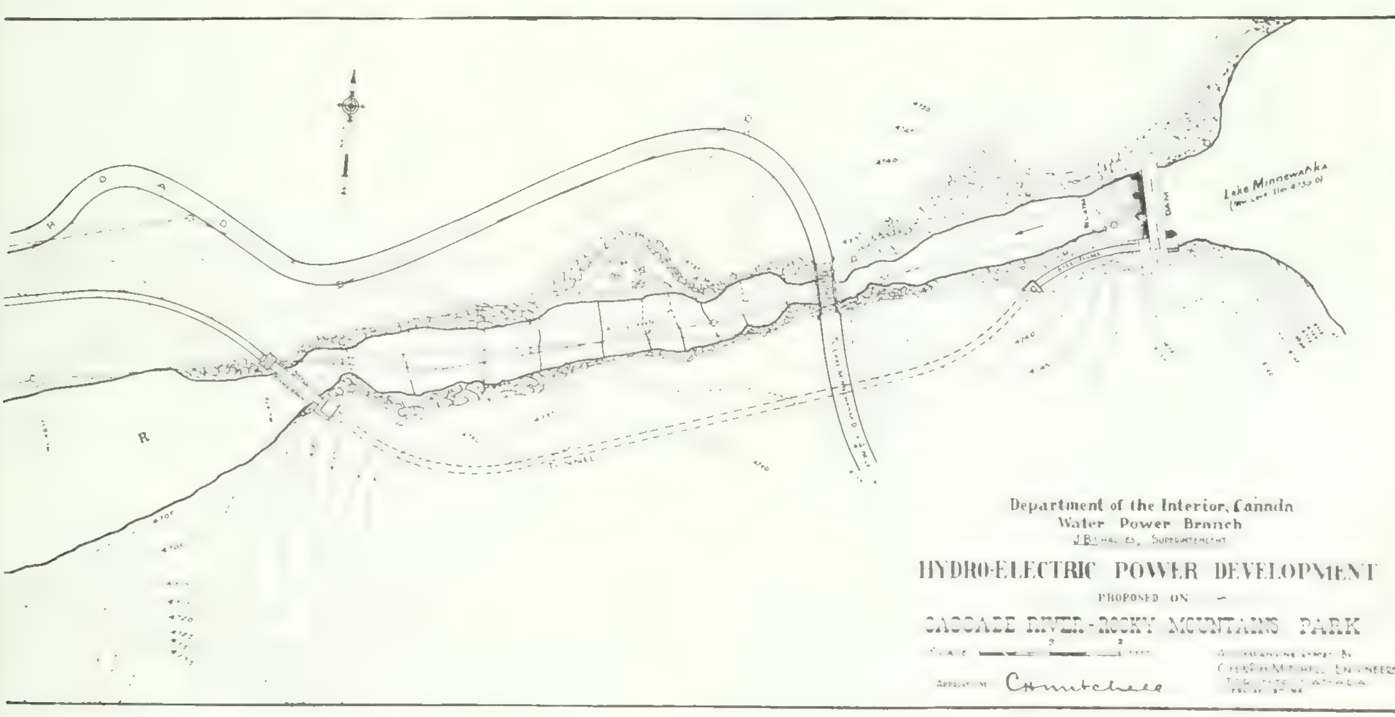
The lower end of the flume would consist of steel, 7-ft. diam., and would have three 48-in. steel feed pipes fitted with valves leading to the three power units in the power station.

In order to secure adequate hydraulic regulation through the long penstock a surge tank, 14 ft. in diam. and 55 ft. high, is proposed, having its top at about 8 ft. above the highest storage water level in the lake. It is proposed to house this tank for protection against freezing, as well as for architectural appearance.

Power Station* and Equipment.—This station is proposed to be of either concrete or brick set on concrete foundations, built entirely fireproof and adapted to continuous operation at all seasons. It is necessary to construct river walls on the outside of the station, the lower to protect the tail-race and the upper to afford a station yard and protection from any high water in the river.

It is proposed to ultimately install three power units, each consisting of a 600-h.p. turbine and a 350-kw. generator, together with an exciter unit direct connected. In the initial development it is proposed to install only two power units and the exciter unit capable of gen-

* In *The Canadian Engineer* for May 7th, 1914, there appeared four competitive architectural designs of this power station.



Development on the Cascade River.

erating of the total output of the station; the building being large enough to include the third unit to be installed at any time in the future when conditions of market warrant.

It is proposed to generate at 2,200 volts and to transmit at 13,200 volts by the use of step-up transformers. All switching and subsidiary equipment would be installed as required.

Transmission Line.—The transmission line, approximately 7½ miles long, would initially consist of one 3-phase circuit, on wooden poles. The line owned by the Canadian Pacific Railway, now in service between Bankhead and Banff, could be readily adapted to the proposed system, the only change required being the replacing of the present conductors by larger ones, sufficient to transmit 1,000 h.p.

Receiving Station and Distribution System. It is proposed to utilize the present receiving station and distributing station and equipment within the town of Banff if it can be acquired at a reasonable price. This system is in excellent condition and is usable with modifications in any extended system of distribution and lighting in the town. As it is proposed in connection with the new system of lighting contemplated in the town and vicinity to extend the distribution system very considerably, it will be necessary to construct several miles of new lines, the wire for which can be secured from the transmission line.

In order to carry out a suitably extensive project of lighting the town and vicinity in an attractive manner, utilizing the most up-to-date types and arrangement, it will be necessary to rearrange the present system and to extend it.

It is proposed that a 3-phase system would encircle the centre of the town, having 3-phase feeders radiating from it. It is expected that the 3 phase lines will prove ample for the complete distribution of power for industrial power service, domestic and commercial lighting and heating to the full commercial output of the generating plant.

A very attractive street lighting system is proposed and special lighting units have been designed. The lighting plans, as at present arranged, provide for 40 standards, 278 bracket lamps and 18 path lamps. Some of the streets will be provided with underground wiring. Street lights will, in general, be operated by the same transformers as are to be used for house lighting, clock switches being installed to operate individual sections of the system at predetermined hours. The lamps indicated on the plan will consume about 120 h.p.

Power Supply and Distribution.—The capacity of the power and transmission system outlined in the foregoing as an initial system of 1,000 horse-power, laid down in Banff, is amply sufficient for some time to come for all the lighting that may be desired, and at the same time will provide power for those various small uses such as motors in bakeries, laundries, printing offices, butcher shops, small machine shops and mills, etc., and for heating.

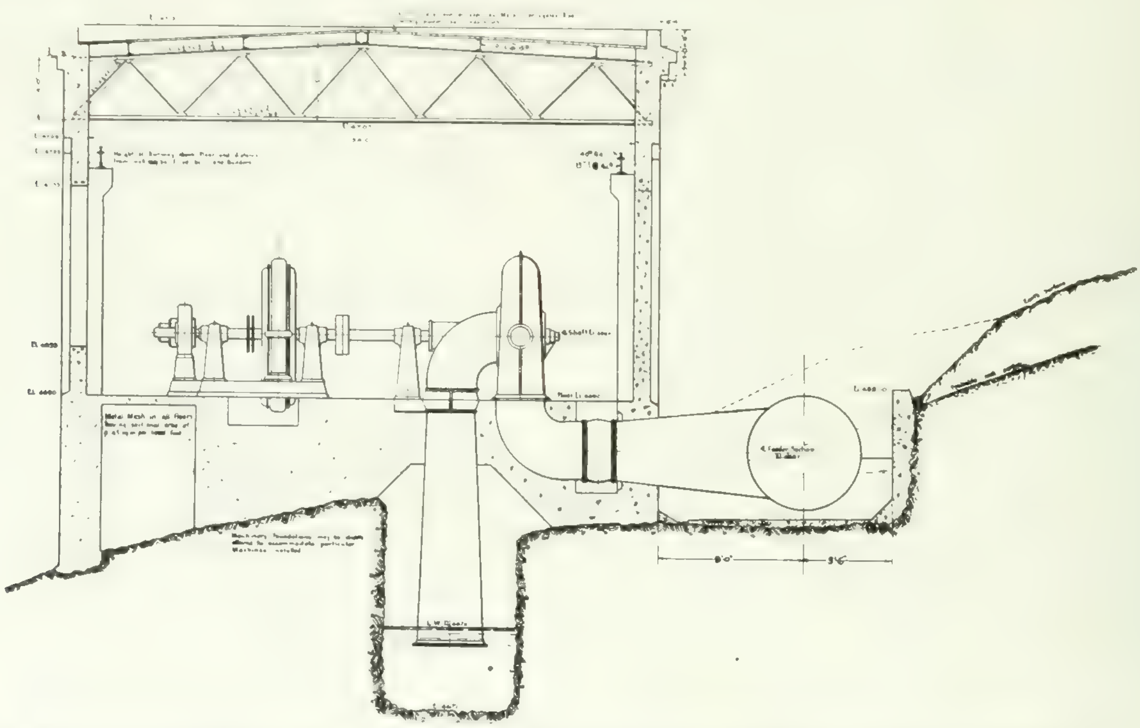


Fig. 5.—Typical Section of Power Station of the Proposed Cascade River Power Development.

Estimates of Cost.—In the following, estimates of cost of construction are based entirely upon the construction of a new system complete from the dam (already built) to, and inclusive of, the distribution and lighting system outlined, as it is only on such a basis that the comparative costs can be readily considered.

The following estimates are based upon the current prices for labor, apparatus and supplies provided and delivered at the location required. If construction is undertaken under conditions whereby these current prices are visibly exceeded, the estimates herein given must be correspondingly increased.

The following estimate is for general works for the whole ultimate plant, but with hydraulic and electric machinery installed only sufficient to deliver 1,000 h.p. in Banff:—

Penstock and flume, including headworks connections, tunnel, river span, wood flume, feeder section and rising section complete ready for water	$34,000.00
Regulating tank, including housing	1,000.00

Power station; foundations and buildings complete with interior work and fittings	12,000.00
Staff house and miscellaneous	4,000.00
Equipment in power station, consisting of hydraulic and electric equipment sufficient to deliver 1,000 h.p. in Banff, together with all subsidiary machinery, such as governors, switching, piping, fittings, etc.	35,000.00
Transmission line complete, total length about 7½ miles, capable of transmitting 1,000 h.p.	11,000.00
Distributing system in and around Banff, comprising receiving station and shop, step-down transformers, town wiring, street fixtures and transformers, the whole leading up to all lighting connections but no lighting	17,000.00
New street lighting system complete, including 60 five-cluster lamp sets and posts, and 250 bracket lamps on poles, together with underground wiring for clusters	10,000.00
Total	$124,000.00
Add for contingencies, engineering supervision and inspection, 12 per cent., say	14,000.00
	$138,000.00

Annual Cost of Operation.—Assuming that (as if for a private company) the funds for the construction and installation of these works were raised by a debenture issue, say, of $140,000 at 5 per cent. to be retired in 30 years, and that the principal and interest is repaid in thirty equal annual instalments. The annual costs of operation and maintenance of the plant throughout will be approximately as follows:—

I. Overhead Charges:

1. Yearly instalment of principal and interest, based on foregoing	$9,100.00	
2. Maintenance account, being an amount set aside yearly against major repairs, renewals and reasonable extensions, 2½ per cent.	3,250.00	
		$12,350.00

II. Operation Charges:

1. Salary, superintendent and general office expenses (within park office)	$2,200.00	
2. Wages of operators at power station	3,000.00	
3. Supplies and minor repairs chargeable to income	1,250.00	
		$ 6,450.00
Total annual cost		$18,800.00

If the foregoing annual cost of operation and maintenance is placed against the total amount of power capable of being delivered by the plant in Banff, viz., 1,000 horse-power, the annual cost per horse-power (24 hours per day) laid down in Banff is approximately $18.80. It is to be noted that steam-generated electric power laid down in Banff in the same manner as hydro-electric, using the usual types of engine under ordinary economic commercial conditions, would, on the same basis, in our opinion, cost not less than $50 per horsepower per year, even with cheap coal nearby.

AN ICE COFFERDAM.

The following practical application of the idea of using ice as a cofferdam in connection with construction work during the winter in climates where low temperatures prevail is cited by Lieut.-Col. Chas. L. Potter, Corps. of Engineers, U.S.A., in "Professional Memoirs" for June, 1914. On a previous occasion the writer had attempted to employ the same method in connection with the construction of the foundation for a small light in shallow water at Lake Memphremagog, but the time had been too limited to effect the freezing. The attempt described below, however, was quite successful, and should contain a suggestion or two for those who have work of a like nature to do in times of low temperatures.

The United States dredge "Warroad" was repaired at Kenora, Ont., in 1912. After being put in the water, a leak showed on one side about 3 feet below water-line. It was not bad at the time; the dredge was needed for work; and the leak was allowed to go. On the laying up of the dredge for the winter of 1913-14, it was decided to try the ice cofferdam method to repair the leak, which was giving considerable trouble.

Owing to the possible necessity of replacing an entire plank, the work was done on a much larger scale than proved to be necessary. On January 25th ice was 18 inches thick in Warroad Harbor. A trench was made 20 feet long, 3 feet wide and 12 inches deep alongside the dredge. Thereafter each day, when the thermometer had been below zero the night before, 1 inch of ice was cut out of the bottom of the excavation. Days when the thermometer was not higher than + 15 degrees during the entire day, there were taken out 1½ inches. After each day's work a small hole was bored to a depth of 5 inches, and dry wooden plugs kept near to plug the holes in case the bit broke through, but it never did. The rate of cutting and the means of insuring a thickness of 5 inches in the bottom of the trench were determined by the custodian of the dredge, as he had no instructions except to get down to the leak. It is probable that he might have gone down somewhat more rapidly, but he was present every day in care of the dredge and there was no occasion to hurry. Parties harvesting ice at that time found that their ponds, left open at night, were frozen about 2 inches during the coldest nights. During the operation, the maximum daily temperatures ranged from + 30 degrees to — 15 degrees and the minimum from + 6 degrees to — 47 degrees. Only once was the minimum above zero, and the maximum was below zero for five consecutive days.

On February 24th—exactly thirty days—there was a trench 20 feet long, 3 feet wide, and 34 inches deep, with 6 inches of ice in the bottom. The thickness of ice in the vicinity was 24 inches. So we had gone down 10 inches below the bottom of normal ice; we still had 6 inches under us; and had uncovered the leak 34 inches below water-line.

The repairs amounted to nothing more than cleaning out a small split in a plank and caulking it.

Mr. H. R. MacMillan, Chief Forester of the province of British Columbia, recently made the announcement that a deal in standing timber in the neighborhood of Fort George has just been carried out by the Government sale to Mr. H. N. Sereth, of the Riverside Lumber Company, of Calgary, of 32,000,000 feet of lumber at the following prices:—Douglas fir, $2.54 per 1,000 feet; spruce, $1.07 per 1,000 feet, and cedar, $1.06 per 1,000 feet. The total value of the timber reaches $37,000, the purchasers to cut this within the next two or three years.

USE AND BENEFITS OF PRESSURE RECORDING GAUGES.*

By J. M. Diven.

RECORDING gauges for keeping a permanent record of steam and water pressures and vacuum have been used by waterworks for many years. In 1891 Mr. Charles A. Hague, in his introduction of his valuable paper entitled "Value of Pressure Records in Connection with Waterworks," said that we should know what is going on inside of steam and water pipes, just the same as we have found out what is going on inside the steam cylinder by the use of the indicator.

In his paper Mr. Hague quotes Mr. Edwin Darling in his 1889 report of the Pawtucket, Rhode Island, waterworks, as follows: "No well-conducted waterworks can afford to be without recording gauges, and, when properly located, they will, in my opinion, pay for themselves within one year" (Proceedings Am. W. W. A., Philadelphia, 1891, p. 77).

These extracts go to show that the value and usefulness of recording gauges were fully recognized more than twenty years ago. We certainly do need to know what is going on inside of the steam and water pipes under our charge, and at all times. A look at the non-recording gauge shows us the pressure at that time, but is no proof or indication of what it was a minute before. The recording gauge does give this information; it tells what the pressure was at any time, day or night, and on any date. It is a constant watchman, just as a water meter is a constant inspector. It keeps a complete and indisputable record of pressure at all times.

In the Pumping Station.—A recording gauge on the steam line is the best possible check on the work of the fireman and engineer. If pumping to a reservoir, under a constant load, the uniformity of the pressure line tells how uniformly the fires are being tended and the feed water applied. An absolutely even line would indicate perfection in the fire room, a ragged line, inattention on the part of the fireman. With properly kept boiler room records, the fireman's work can be accurately checked. A sudden drop in the pressure line should correspond exactly with the record of fires cleaned or boilers blown off. A quick drop or sudden rise at any other time indicates improper firing.

With a direct pumping system, or where pressure has to be raised for fires, a less even steam line is to be expected; but a comparison of the steam and water charts will show how quickly the boiler responds to a sudden demand for more water pressure, by restoring and holding the pressure when the work of the pumping engine is suddenly increased. A direct pressure pumping system requires greater care and alertness on the part of the engineer and fireman, and the recording gauges are the best possible means of knowing how well they perform their work. Perfection would mean a line equal to one drawn with a compass or straight edge, according to the style of chart used, and the nearest approach to this indicates the best work. A ragged, zigzag line means inattention and carelessness, or something wrong with the boilers, steam lines, engines or pumps. It rests with the chief engineer or superintendent to find out which is at fault, and to correct the fault; the gauges cannot do this, they can only tell in positive language that something is wrong.

The presence of recording gauges is an incentive and stimulus to the men to do better work. They know that they are constantly watched; that a constant and indisputable record is being made of their work. The superintendent, when he visits the pumping station, or when the gauge chart is placed on his desk, has a perfect check on the work of the pumping plant force, and a record he can preserve for all time. When he has occasion to call an engineer or fireman to account for laxness, he has before him, to confront the culprit with, an undeniable record of his work. A poor pressure line may not be the fault of the engineer or fireman; it may be due to poor fuel, a leaky or sagging steam line, bad feed water, poor draft, or engine trouble; but the engineer is just as much at fault, for not promptly recording and reporting such troubles, as he would be for neglecting his work, or not keeping the fireman up to his part of it.

If good pressure charts are obtained for a while, but constantly and uniformly get bad, it indicates either that the plant is wearing out or being overloaded. If both good steam and water charts are obtained when the plant is pumping, say, 5,000,000 gallons a day, and grow more and more ragged as the pumpage is increased, they surely indicate that the pumps or boilers, or both, are being worked beyond their economic capacity. If the pressure lines grow in irregularity, when there is no increase in the work, they indicate that some part of the plant is wearing out or is in bad order, and needs overhauling.

Steady lines of the steam charts indicate uniform and careful firing, and a steam plant in good condition. Ragged gauge lines indicate either poor and irregular firing or bad condition of the boilers. If the feed water is a scale-forming water, the poor gauge lines bear out the evidence of the coal scales, that the boilers need cleaning.

A fireman cannot fill his firebox, then light his pipe and go out of the fire room to seek a cool place, and maintain an even line on his steam gauge charts; but must stay by his fires, fire frequently and lightly, and keep clean fires. Knowing how completely he is on record he will be careful, and will also keep a record of everything that might affect his record, such as poor fuel, time of cleaning fires, blowing off boilers, etc. The latter records, which might otherwise be neglected, are in themselves of sufficient value to more than pay the cost of the recording gauges, if no other benefits were obtained.

The vacuum gauges should also be recording, to indicate the condition of the engines and pumps, a falling off in the height of the vacuum line indicating leaks that mean more coal. The lines on the vacuum gauge charts should not vary much. If a vacuum of 27 can be obtained one month or year, it should be maintained the next month and year. If a higher vacuum is maintained with one kind of packing than with others, the one holding the high vacuum is the best, and probably the cheapest, though much higher priced than the others. The difference in cost might be made up many times in the saving of fuel.

No engine room is complete without at least three recording gauges, as the operation of the plant cannot be properly checked and governed without them. They also insure better work on the part of the operatives.

Many times the recording gauges create a spirit of rivalry between men on different shifts, through an effort on the part of each shift to do better than the others, to show more even lines on the charts; thus causing all to do better and more economical work.

There should be a certain economical relation between the steam pressure and the water pressure. When this is

*From the March, 1914, Journal of the American Water Works Association.

worked out it should be as closely maintained as possible. An unnecessarily high steam pressure, even though it gives a very uniform gauge line, is not economical.

On the Distribution System.—On gravity supplies or pumping plants, in cities of considerable size, a gauge, or gauges, should be placed on the distribution mains at some central point, or at typical points. If more than one service, high and low service, each should have a recording gauge. It is well, when practicable, to take gauge services off of large or leading mains, where they will not be liable to the great fluctuations in pressure frequent on smaller distribution pipes.

Of course, there should be a gauge in the office, where it will be under the eye of the superintendent when in the office, and, at other times, of some other officer or employee of the waterworks, of the night watchman, if one is employed; one in the superintendent's house, for reference at night, is convenient, but, with telephone connections, not so necessary.

The connection to the gauge should be entirely independent of all other service to the building in which it is located. It should be of good size, not less than ¾ inch, and placed where it will be in no danger of freezing, as there cannot be a circulation in the gauge service and an accurate record of pressure on the main at the same time, without the expense of a double service, in which a free circulation would be doubtful, unless it were very carefully planned, and even then there would be an item of friction in the smaller pipe, that would be difficult to account for. Of course, water cannot be allowed to run in the gauge supply pipe, in cold weather, without totally destroying the value of the gauge record.

The gauge service should be so arranged as to be easily blown out or flushed, to avoid all possibility of stoppage, by an accumulation of sediment. While a ¾ inch or larger service is recommended, the gauge operates with a very small opening; the object of the large service is to avoid stoppage.

Location of Gauges.—The pumping station gauge comes first, and, in smaller plants, is all that is required. Larger plants should also have an office recording gauge. Cities or towns with two or more services should have a record on each service. Large cities should have recording gauges at various points on the distribution system, notably near the congested value districts.

Gauges can be placed in the residences of employees of the works. They require little attention, winding of clock, changing of charts, and seeing that the pen, where ink records are made, is kept properly filled.

The fire department stations are convenient places for recording gauges, and the fireman's interest in the water pressure is enough to insure proper attention. For municipal plants, police stations can be utilized, if they are better located than the fire engine houses, that is, on larger supply mains.

Very long services should, naturally, be avoided, both on account of the expense and the danger of stoppage in long lines of small pipes. The service should be of durable material, and, with corrosive waters, iron services should be avoided, as an accumulation of iron rust would stop up the minute orifice of the gauge.

The Benefits of Recording Gauges.—The benefits of recording gauges are many; they have been known to stop law suits, where actions for damages caused by low pressure were threatened. The recording gauge settles many disputes concerning pressure at time of fires or other times. Often complaints of low pressure are made, not enough to supply the upper floors of some buildings. A nearby recording gauge demonstrates that it is a local trouble, within the building. These complaints are frequently that the pressure is low at certain hours of the day or night, but a gauge chart showing a uniform pressure at those hours, demonstrates that it is local use of water, in the building itself, or in the distribution system near it, that causes the trouble.

The recording gauge charts show the effect of cold weather on the water supply, the low pressure lines on the chart in freezing weather indicate the extent to which water is being run to prevent freezing. They also reflect the hot weather use of water; a low pressure line on the chart at night tells of water allowed to run on lawns all night.

Portable Recording Gauges.—All parts of a city cannot at all times be covered by recording gauges, so that the story they have to tell is incomplete. Portable recording gauges set up in various places for short periods make a fairly complete record of the conditions of the supply at points on the distribution not covered by regularly established recording gauges. Such records in large buildings, factories, etc., where the fire hazard is great, are particularly useful.

A gauge set up for a single day gives a valuable record, as it shows a comparison between the day and night pressure at some particular point.

Portable gauges can, with advantage, be connected to fire services, as, on such services, they would be free from the fluctuations due to the use of water on the premises, or, if the fluctuations existed, they would reveal improper use of water from the fire services. With a small portable house or box to protect them, gauges can, in warm weather, be attached to fire hydrants, to make a record of the pressures on the mains at any point. Summer records of this kind, made on the outlying mains, mains in sparsely built-up parts of the city, on long runs of small distribution pipes, and on the outskirts of the town, are of great value and interest.

Preservation of Gauge Charts.—Charts should be permanently kept as a part of the records of the works; as part of the history of the plant. They should be conveniently filed for reference at any time. For straight line charts suitable albums or scrap books make a convenient file. For round charts the scrap book form, though suitable and convenient, is bulky, as a page would be required for each day's chart. Substantial pasteboard boxes of the right size to hold a year's charts, are convenient. These can be labelled with the year, and, where several recording gauges are in use, with the location of the gauge, making it convenient to refer to the charts from any gauge at any time.

It is interesting to look over the old gauge charts, also often instructive. A new waterworks, with new and clean pipes, with pumps not over-crowded, and ample size force and distribution mains should show a steady line, with slight fluctuations, and near the outer edge of the chart. As the consumption increases, the line grows less and less steady, and converges toward the centre of the chart, showing the reduced pressure due to greater friction in the mains. The raggedness of the pressure line on the chart also increases with the age of the plant, as the mains become tuberculated and clogged with sediment. Finally, the consumption has gone beyond the pump capacity; a new and larger pump is installed, and the pressure line again approaches the outer edge of the chart, and becomes more steady, but still shows greater fluctuation than when the plant was new and working at a comfortable rate.

Notwithstanding the new pumping engine, the results are not entirely satisfactory, when compared with the

earlier charts; the pumping engine, though of ample capacity, is working harder than the original pump had to work; both the water and steam pressure lines on the pumping station gauges have approached nearer to the outside circles. Higher water pressure has to be maintained on the pumps to keep up the pressure on the distribution mains. A comparison of the gauge charts from year to year shows this steady gradual increase of the pumping station pressures, and, at the same time, lessening of the pressure at the office and other points on the distribution system. Finally, the pumps are unable to give a proper pressure in the town though they have a capacity even greater than the demand. A new force main is installed, and the original conditions are nearly restored, though the pressure lines are not quite as steady as at first, owing to bad condition of the pipe system. A thorough cleaning of the mains and distribution pipes restores the steady pressure line near the outer edge of the circle. So, the gauge chart tells us when a new pumping engine is needed, when to install a larger force main and feed mains, when the mains need cleaning.

A study of the old gauge charts tells a story, relates a plant history, as old documents or old letter files tell the story of the community. This is especially so if the charts are carefully and properly labelled before they are filed away; the date, the temperature and weather conditions, notes concerning fires, breaks in mains, engine or steam plant troubles, etc.

A frequent examination of the files of old charts should be made, as they tell an interesting and valuable story of the operation of the works, and give valuable hints for needed changes and improvements.

There is now an instrument for ascertaining from the pressure lines on circular charts, the style now mostly used, the average daily or weekly pressures. These results can be conveniently plotted, so as to show compactly the average pressures throughout a year, or many years. The plotting of two or more years on the same sheet, using different colored inks for the different years shows compactly the comparative pressures for the equal seasons of each year. Temperature and weather condition notations would add to the interest of these charts. For instance, the month of February in one year shows a steady and good pressure line, while the same month of the next year shows low pressure and a ragged line. The temperature reference shows for one year a moderate temperature, for the other steady cold weather with extremely low temperatures. Without the temperature record the great difference in pressure would be hard to explain.

Consumption records should also be included, to account for the probable steady decrease in average pressures from year to year. Like the February temperature record, the mid-summer temperature and precipitation records would also tell their story.

Recording gauges are useful in so many ways, give so much information and so good a record of the daily operation of the pumping plant and the condition of the plant, that they are indispensable, and no well-regulated waterworks should be without them, and none can have too many. A superintendent cannot have accurate knowledge of the operation and condition of the plant under his supervision without using pressure-recording gauges. It is false economy to try to do without them. The cost of installation and maintenance is small, trifling, as compared with the benefits.

Pressure-recording gauges require little care, if daily charts are used, and they give the best records—daily changing of the charts, winding the clock, and filling the pen, are all that is necessary. The supply pipe should be blown out occasionally, to keep it clean, and the clock kept regulated, so that the time records will be accurate. This last item is important, should disputes arise, concerning pressures at time of fires, particularly in towns where an increased fire pressure is required. The rise of the pressure line in the chart should disputes arise, concerning pressure at time of fire alarm. In this connection, some care must be exercised in placing the charts, to see that they start on the correct time line. Some troubles have been caused by carelessness in this, occasionally, for some unapparent reason, the gauge chart does not revolve, though the clock is going. This may be due to careless securing of the chart, or to putting in two charts at once, the under one revolving all right, but not receiving the impression of the pen or pencil, the outer one slipping on the smooth surface of the lower one and remaining stationary.

DANGERS OF ACETYLENE GAS

"That acetylene gas lighting plants require most careful handling and that no such plants should be installed or maintained in the basement of any buildings—these are the lessons taught by the recent catastrophe at the hotel at Macoun," says Fire Commissioner R. J. McLean, of Saskatchewan, in a recent bulletin.

Hitherto too large a measure of indifference and consequent carelessness have existed in regard to both gasoline and acetylene. No more than a passing thought has been given to the explosive qualities of either and whether location of such plants inside buildings materially affects the risk of life and property has received scant consideration.

In view of this disaster public interest has been aroused and advantage is taken of the opportunity by the office of the Saskatchewan fire commissioner to indicate the nature and danger of acetylene. Its advantages as a light in cases where electricity is not available are undoubted. Amongst them are the following: The light is brilliant and colorless, the flame gives off less heat and poisons the air less, its odor is so strong as to be easily detected, its vapor is so light as to be readily dissipated, the bore of the burners is so small as to permit very little of the gas to escape.

On the other hand its dangers are so great as to demand the strictest precautions as to the conditions of generator, storage tank and piping and also to location of these. As a gas it is so highly explosive that air containing one-thirteenth as much acetylene is more explosive than gunpowder. Acetylene is produced by the union of calcium carbide and water. The water may be fed to the carbide or vice versa, but feeding the carbide to the water is much safer. In either case any generation or superfluous gas, due to lack of feed control, is highly dangerous. The danger is generally near the generator. A defective feed tube or the opening of a seam, caused by the freezing of the water seal, may cause an escape that has only to come into contact with a light, a red hot cinder or even a pipe in a smoker's hand to do more harm than dynamite.

Should an acetylene generator—or even a gasoline carburetor—be permitted in any basement of any home or public building? is the question which is being asked to-day, and the answer is, No, any such installation is not advisable. All such generators should be placed outside at a safe distance. Whatever difficulties may arise as to the methods of heating such outside buildings—an acetylene machine will freeze if placed in a building that is not warmed—are such as should be overcome at all costs as compared with the danger of having an inside installation. It is better to be safe than sorry.

The Macoun disaster cost ten lives and as many injured and the absolute destruction of $35,000 in property. A leakage from an unknown cause, coupled with the presence of a fire in the furnace or an open flame in the same basement was the origin of the explosion. There are many homes, churches, and public buildings in Saskatchewan lighted by acetylene. No thought is given to the danger, and no thought was given to this sad case. An appeal is hereby made for safety first and safety all the time. Consider the danger to human lives and property and guard against it.

POINTS WORTH NOTING IN CONNECTION WITH ROAD IMPROVEMENT.*

By Major W. W. Crosby,
Consulting Engineer, Baltimore, Md.

WHEN the improvement of a locality's public roads is begun on comprehensive lines and according to some definite scheme, several important questions immediately present themselves for consideration and decision. Among them are:—

1st. The selection of the roads to be improved, such a selection being necessary for obvious reasons.

2nd. The organization of the administrative and executive forces under the laws governing the work.

Too often the speaker has observed an apparently insufficient comprehension of the importance of this latter question—perhaps more especially in those cases where an existing organization, developed for carrying on certain limited operations, was suddenly loaded with the new work in an amount several times as great as the earlier burden. In such cases it has been too frequently the practice to attempt to expand the old organization, by adding new units of the same character to it, so as to carry on the new work when what should have been done was to recognize the different character of the new work, its preponderance perhaps, and its peculiarities from any point of view, and to recognize the entire department so as to provide such a machine for the combined operations as would properly and efficiently produce the results desired. It is coming to be realized—possibly through the good results obtained from some efficiency experts—that proper organization is necessary for successful results, especially when large scale operations are to be attempted, and that it is futile to attempt to secure efficiency simply through the multiplication of units. Proper co-ordination or relations between the units must be provided, and the units themselves must each be composed of the best quality of the available material so arranged as to work successfully and without constant failures.

3rd. The selection of the methods and materials to be used in the work itself. The importance of this question can readily be appreciated, but perhaps a word or two on it may not be out of place here. In almost any locality the opportunity is offered for a choice between two or more methods and materials for improving a road surface. Now, while with money raised by annual levies, considerable latitude in the expenditure of such funds may seem to exist, such is not the case with borrowed funds. In the one case it may be said that it is the "income" which is being spent while in the other it may be said to be the "principal." It is at least not as extravagant to spend one's income for things of a temporary nature as it would be to waste one's principal on them. Therefore, in the expenditure of borrowed funds for road improvement every effort should be made to secure results that will prove of the greatest possible permanence and cheapest in the long run—not necessarily cheapest in first cost. On the other hand, it is useless to look for a "permanent" road, if by the expression is meant a road that will not require yearly expense for its up-keep. In the historic words, "There's no such animal." All roads need maintenance, and in calculating the cost of a road, this expense for maintenance must be added to the interest on the first cost in order to secure figures which will enable a comparison to be made on a monetary basis between the value of the results from two differing methods or materials of construction. It will only too frequently be found to be the case that mistakes from the point of view of expense have been made by the vain attempt to secure, regardless of first cost, a "permanent" road surface and that a saving would have been made had a cheaper surface been laid and replaced as needed from time to time. This is especially true where traffic conditions are in a changing state. On the other hand, it must be remembered, as before referred to, that the other extreme of cheapest first cost may be equally undesirable as a refuge for the solution of the problem.

Good location of the road, satisfactory grades for it, sufficient width of right-of-way, substantial and enduring bridges and culverts, proper drainage and adequate foundations are some of the most permanent features of modern road work. They should be had at almost any cost from borrowed funds, and by securing them the borrowing of money for the work is best warranted. For the road crust itself to be placed as a wearing surface over such basic items, excessive expenditures from borrowed funds are neither warranted nor logical. But if borrowed money has to be used for these wearing surfaces, then every effort should be made to secure in its expenditure the greatest possible value in the long run for the results. The term of the bonds, the future of the traffic, the availability of materials, the probabilities as to maintenance, etc., etc., will all affect the decisions in any case, but perhaps enough has been said to indicate the complexity and importance of this question.

Just at this point it seems pertinent to the speaker to offer a word or two more on a closely related point to which reference has been made. If not already an accepted axiom, it should be that no bond issue for road improvement should be made unless the proper maintenance of the physical results of the bond issue is amply provided. Of course, that the expense for maintenance should in no case be met by borrowed funds needs no argument here. The probabilities for maintenance—that is, consideration, of the needs for and sufficiency of the funds for this work, of the probable promptness and thoroughness with which it will be performed, and of the character of the authority over it—are bound to influence decisions in the matter of the selection of road crusts to be built. If maintenance funds are for any good reason bound to be insufficient for properly keeping up one form of crust, then it will be necessary to incur the greater expense for first cost of a form less expensive to maintain, even if the long run cost be greater, because unless the road crust is to be so maintained as to give its greatest possible value, there is no excuse for putting any borrowed money into its construction. If the maintenance to be expected is not to be prompt and thorough, then the need for attention to up-keep should be reduced as far as practicable by modifications in construction. The culverts and drains may thus have to be built larger than they otherwise need be if they were to be kept continuously free from obstructing matter. If the maintenance is to be turned over after construction to a body other than that in charge of the construction, allowance should be made in the solution of all construction problems for the probable lessened interest of the second body for the proper up-keep of the construction done by other parties.

A paper on each of the questions referred to above might well be presented for the consideration of this audience, but while the speaker was given considerable leeway in his selection of a subject and has thought it advisable to refer briefly to these matters as preliminary to the subject indicated to him as especially desired from

*Read at First Canadian and International Good Roads Congress, held at Montreal, May 19th, 1914.

him, he will leave to others further dilation on the points mentioned and proceed with the question:—

4th. The securing of proper work in the construction itself. The speaker does not intend to attempt to cover all the points on which remark might be made but merely to point out and to explain as may seem advisable such points as are not usually covered by specifications or are of especial importance and, to him at least, worthy of further emphasis. Furthermore, it may be that some of his remarks may seem to be out of place under this topic and that they should have been made under the preceding headings. In such case he asks the indulgence of his audience for the apparent disorder, but hopes that a further reason for his introductory remarks may be apparent.

In the construction of macadam roads—using the term "macadam" in the broader sense of meaning a road-crust composed of gravel, broken stone, or slag within certain limits of size, thoroughly compacted before any fine material shall have been added, and then having its voids filled with fine material or "bound" by the combined action of watering and rolling with the addition of only the needed amount of fine material such as sand, stone dust, etc.—it is generally specified—but less generally practised—that the "subgrade" or earth surface, on which the macadam is to be spread and built, shall be made firm and even before the macadam material shall be spread. The importance of this specification is often not realized by inexperienced engineers and contractors. To the former the clause seems frequently to be cautionary and not mandatory, while to the latter it generally seems fussy and unnecessary. To both, as well as to you, the speaker would say that this clause is important and absolutely necessary. Unless it is carefully observed the contractor will have trouble and extra expense in performing his subsequent work of compacting his macadam and the engineer will not be able to secure the results specified and desired for the road-crust.

An improper subgrade will mean that an excess of macadam material will be needed in order that a clean compact layer of macadam of the minimum thickness required for strength shall be finally had. It will mean greater difficulties in rolling the macadam and may even prevent the proper degree of compaction from being secured and thus the presentation of an inferior article for acceptance and use. This, of course, means shorter life, increased maintenance expense and greater waste of borrowed funds in a channel of doubtful, or at least questionable, use of such funds. If the subgrade is left so loose or soft that it is forced up into the macadam material during the rolling of the latter, any hope of securing macadam from this material is lost and the broken stone, gravel or slag under such circumstances can only be considered as an addition to the subgrade—and quite likely an unnecessarily expensive one—on which a macadam or other crust may eventually be built.

The same remarks concerning the necessity for a firm subgrade in the case of gravel roads where the crust is composed of suitable unscreened gravel, though in the latter case the fine material present with the stones may help somewhat to overcome the dangers incident to placing the gravel on the soft subgrade. Even with concrete road crusts and foundations, it is now generally agreed, for the sake of better and more lasting results, that it is desirable to have as good a subgrade as practicable.

Another point that is too often slighted in connection with macadamizing is the proper rolling of the macadam material. It is usually specified that the rolling shall proceed until the material shall be thoroughly compacted, firm, and even on the surface or until waving ahead of the roller is imperceptible. An old rule for the guidance of inspectors is to have the rolling continued until the material is so firm that no movement in it is discernable adjacent to, but outside of, the fact as one walks over the rolled surface. The speaker has found too often a tendency among inspectors to require too little rather than too much rolling, and of course the average contractor's foreman will yield to, if not actually encourage, this tendency to slight the rolling. Perhaps, therefore, a word or two of explanation as to why sufficient rolling should be done may tend to bring better results. When broken stone, for instance, is spread on the subgrade from piles on dumping platforms or piles alongside the road, the voids in the stone layers are approximately fifty per cent. of the mass. It is obvious that the denser the layers can be made the better wearing surface will be produced. By proper rolling the original voids can be reduced by forty per cent. (or to 30 per cent. of the mass) though to secure this result the rolling must be had before the addition to the screenings. The addition to, or even the presence of fine particles in, the macadam material before the rolling of the latter will interfere and often prevent the desired compaction being secured.

The tendency of most contractors' foremen is perhaps naturally to roll insufficiently the macadam material and then to attempt to secure a bonded surface by the addition of fine material and water with more rolling. The results of this process can but be inferior to those secured from the same materials but with proper rolling before the addition of the screenings. It should be understood that the rolling of the macadam material does something more than compress the layer. Properly done, the rolling not only compresses the layer but it also works the pieces of stone together so that the angular pieces fit into the voids of the mass and mechanically interlock, thus strengthening the mass against a tendency toward displacement. Further, under proper rolling the stones at the surface at least are disposed so as to present to the wear of traffic a flat side instead of an edge and consequently to sustain better the wear coming on them. These facts explain the better wearing qualities so noticeable in macadam built with a minimum of fine material and the inferior quality of an old-fashioned "stoned road" where the crust was probably unrolled and the coarser pieces are merely set in a matrix of mud like plums in a pudding.

It has been said, "First get your coarse material (meaning that forming the body of the road crust) where you want it and then fill the voids remaining with the filler to be used in any case." Doing so may account for the already recognized greater strength of rolled and grouted concrete over that of mixed and placed concrete.

One more thought on construction details is concerning the application of the fine material. It is desirable from many points of view, some of which have been mentioned, to keep the amount used to the minimum necessary. The better way to do this is to apply it in thin layers and only as many of them as evidently needed. The application of a single thick layer means the formation of a temporary cushion which interferes with the proper filling of the voids in the macadam and its final bonding by the aid of water. After the macadam has been thoroughly rolled, a thin layer of fine material of the proper character should be spread and then rolled and watered. Bare places then appearing may then be covered again with another thin layer, and so on until the road is finished. If, then, an excess is desired for any reason to be left on the surface, it can readily be applied.

but if an excess has been first applied, the removal of any part of it, no matter how desirable, is difficult, if not impossible.

The speaker has referred, in his remarks on the work of construction itself, mainly to macadam roads because it seems to him that the bulk of the work in view is probably of that character. Occasionally one hears that "macadam is a thing of the past," but this is, as the report of Mark Twain's death was at one time in his words then, "an exaggeration." M'Adam's principles will be in use for many years yet, and good macadam properly built will be the economical road crust for many localities for a considerable future period. If necessitated by conditions, it can be treated in one or more ways with pitch or pitch compounds, so that its availability is widely extended. But its underlying principles still prevail, hence its selection by the speaker for limited time of his remarks on this point.

The expenditure of large sums of money on a section of road or of any borrowed money for road improvement is based on the single principle that an investment is thereby made which will return a profit to the ratepayers. There is no other excuse for the expenditure of more funds than is necessary to preserve things.

The profit may be direct, indirect, or both. It may often be that such expenditure as the installation of necessary drainage facilities will permanently reduce the annual cost of maintenance. This is a direct financial benefit. Or it may be that such an expenditure as that for reducing a bad grade will permit heavier loads to be handled with the same or less effort. This is an indirect financial benefit. But in either case it is appreciable and justifies a certain investment toward its end. If the sum of all the direct and indirect benefits does not prove greater than the cost of the investment, then the borrowing of funds for the purpose is not justified. Therefore, when funds have been borrowed for road improvement, in order that their investment shall be profitable, it is necessary to expend them with discretion and in such a way and to such ends that waste, lost motion, or inefficiency and extravagance do not result. The cheapest possible results, compatible with economy, in the long run must be secured and the most results must be secured from the money that are practicable. Otherwise the situation will be like that of the man standing on miry ground and trying to extricate himself by pulling upwards on his boot straps. The imagination will finish the description better than can the speaker.

At the works of a leading steel manufacturer at Munich, interesting experiments have recently been carried out with a new process, the invention of a Swiss engineer, O. Widmar, of Zurich. According to this process, tool steel is produced from iron by chemical means without remelting. Experts of different nationalities were present at these experiments, and they report most favorably on the new process.

It has been reported in Calcutta that the Punjab Government has entered into an agreement with the Kashmir Iron Mines and Power Syndicate, Limited, providing for the erection at Dandot, of a factory for Portland and other cements, limes and plasters. In addition to the concession, the agreement confers a double 10-year monopoly on the company in regard to the manufacture and supply of cement, etc., in the Punjab. During this period no other Government land in the Punjab is to be allotted or leased, nor any other concession granted for the purpose of manufacturing Portland cement. During this period the Government are also bound to purchase from the company all the Portland cement, etc., which is required for works carried on by them, such as works for municipalities and local bodies. On the strength of the above it is promised to form a public company, to be called the Punjab Cement Company, to be floated privately.

PRACTICAL DESIGN OF STEEL STRUCTURES.

THE following notes formed part of a paper read before the Cleveland Engineering Society by Mr. Jos. R. Poe, President of the Poe Engineering Company, of Cleveland, O. Mr. Poe laid great stress upon the importance to the designer of practice and experience, in the fabrication and erection of structures. Dividing the practical design into: (1) Laying out and detailing in the office; (2) Fabrication in the shop, and (3) Erection in the field, the connection between the three were well explained:—

You may ask, what has the fabrication and erection to do with the design? It is just this: You must consider the cost of fabrication in the shop and the facilities for erection in the field. For instance: Pieces might be designed too long for erection with the derrick as constructed. An instance comes to mind where some bridge chords were designed to cover four panels; they were light and easily shipped, but the boom was too short, and, consequently, it became necessary to cut them in two. Permission had to be obtained from the engineering department, and also from the supervising engineer; then new splices designed, made and shipped, and holes drilled in the chords in the field. This caused considerable delay and loss, simply because the designer had not been practical.

Laying Out.—Upon the laying out and detailing in the office depend the success or failure of the subsequent operations. Even the profits of the company and the operation of the machine (if it be a machine) are dependent upon this first step of the practical design. After the contract is awarded and the stresses computed, the practical designer gets in his work. A theoretical designer will invariably pick out sections which are not common stock, and hence require special rolling. The professors in the technical colleges try to teach the students which are standard and which are special shapes, but most of them forget it until it is demonstrated in the hard school of experience.

The mills will not make a special rolling, when busy, until they have a large tonnage of that section. Now, if the common stock sections be used, they can be obtained from the stock pile at the mill, or if in a rush, can be secured from a jobber. If they be extra long or in large quantities an immediate rolling will be made. A few of the common sections might be mentioned here:—

Angles.

2½ x 2½ x ¼ and 5/16	3 x 2½ x ¼ and 5/16
3 x 3 x 5/16 and 3/8	3½ x 3 x 5/16 and 3/8
5 x 3 x 5/16 and 3/8	5 x 3½ x 5/16 and 3/8
6 x 3½ x 3/8 and 1/2	6 x 4 x 3/8 and 1/2
6 x 6 x 3/4 and 1	

Channels 6 in., 8 in., 10 in., 12 in. and 15 in. lightweight sections. Eye-beams same depths as channels, but including 20 in. and 24 in.

Plates are generally rolled to order. We are making a practice of ordering plates 48 in. x 10 ft. for details, when the plates are to be cut irregular. The shop then cuts them to the best advantage and what is saved is good stock. Ofttimes they use plates from the scrap pile and keep the 48-in. plates for stock. The designer should also watch his own stock and use from it whenever possible. Structural shops will often request permission to use some heavier section or other section equally as heavy as the design, simply because they have it in stock with very little call for it. Permission to use this section will expedite the contract and work to the advantage of both contractor and customer.

In laying out and ordering material, the main members should be ordered to the best advantage, avoiding extra cutting and waste in the shop. The details should be ordered liberally and should be capable of lending themselves to any changes that may be found necessary as the work of detailing progresses. After the work of laying out and ordering material comes the detailing, which is done by a corps of embryo engineers and practical draftsmen.

The detailing and checking are simply the making of pictures of each member, capable of being reproduced in the shop. Along with the detailing go many phases of the practical design. Members must be made the proper size and length to facilitate shipping and erecting in the field. Of course, this should be taken care of in the preliminary design, but the detailing is the final judgment. Every member should be checked for strength, shipping dimensions and erection, as well as mechanical errors. Every possible rivet should be driven in the shop, but none that will prevent the members from sliding into place quickly in the field. Often rivets have to be cut out in the field before members can be erected, which means the delaying of from six to ten men and a derrick or crane. This unnecessary delay would pay the expense of driving from ten to twenty field rivets.

A good example of driving rivets in the shop to facilitate erection is found in the columns of an office or mill building. All connections for beams and girders should be riveted to the columns, which reduces the shop work on the beams, most of which will not have to go to the riveter, and also expedites the erection. For instance, take a beam in an office building. The connection is riveted on the column, the beam is dropped into place and the connection forms a shelf that supports it until it is bolted.

While speaking of columns, let us digress a little and touch on the footings. No grouting should be allowed, because it is liable to disintegrate and leave the column resting on three points of support. The writer has seen columns where a two-foot rule could be pushed under them with very little trouble. One well-known railroad requires concrete to be poured one-half inch above grade and then dressed down to a smooth bearing, while others sometimes use sheets of lead under the column.

Steel should be designed to avoid the use of falsework wherever possible. Take, for example, cantilever and rolling lift bridges. A special traveller climbing up the back of a rolling lift bridge has become a familiar figure to all of us. This is a very good example of the absence of falsework and serves two purposes: first, it keeps down the erection cost; and second, it allows an open channel and free use of the old swing span.

In every steel structure each member should be designed, if possible, to be self-supporting, or capable of being guyed in place until the proper tie member is erected. Splice plates riveted in the trough of the channels are a hindrance to the easy erection of bridge chords. These plates necessitate the sliding of the chord in place, while the post and diagonal prevent this motion and require a straight drop. All structural members should be designed, where possible, to allow them to be dropped vertically in place. The weight of the member thus aids the erectors in catching the holes.

Proper clearances should be provided. Make the outside dimension of the entering member one-eighth of an inch less than the inside dimension of the entered member. The line of rivets next to the splice should be omitted.

All extra long members (and, in fact, any unusual construction) should be submitted to the superintendent of erection for approval. Failure to do this often catches the erectors unprepared and causes delay. It has necessitated the cutting of members in the field.

The æsthetic design should also be considered. All exposed members of a steel structure should not only figure strong enough, but should have the appearance of strength. The engineer will thus avoid criticism from the general public and the press. The writer remembers a certain important member in a steel structure that was made too small for its length. It figured strong enough, and it was made that way. Every engineer who looks at it remarks that it is too small, and it is needless to say that the designers have regretted its construction many times. However, it is still standing, although it has received some very hard knocks, one of which buckled it, yet it did not fail.

Structural steel frames for buildings are becoming very common, and have created a demand for a construction which is cheap, yet good. Engineers and contractors are studying all types of construction to find the one best suited to their needs.

An important item in the practical design is the number of rivets to be driven. There is a tendency among the better class of draftsmen to put in too many, when in doubt about a connection. On the other hand, another class of draftsmen will skimp every connection. Too many is poor business, and too few is bad design; neither should be tolerated.

To expedite the work in both office and shop, certain standards must be followed. One of the most important is the number of duplications. Beams should be made alike as far as possible; likewise the shelf angles supporting them. Now, if every different column changes, the beams or shelf angles must change. This requires more careful checking in the office and more pieces to lay out and store until ready for fitting up. The fitter must find the correct angles from many small piles instead of taking any angle from a certain large pile. This objection can and probably will be overcome as the call for these sections increases.

Another item is the ease with which the rivets can be driven. For instance, a column made up of two channels with their toes turned in and laced is a very hard column to rivet. It may be impossible to drive them with the machine, hence the rivets must be hand-driven. If they can be driven with the machine, it will be necessary to lift the machine up after driving three, at the most.

Laced members are expensive in the shop and should be avoided if possible. In fitting up, every bar must be bolted in place and the bolts removed one by one as the riveting progresses. With plate construction, only 15 to 20 per cent. of the holes are bolted, the others being open. The riveter runs down and fills them, then back again, filling the holes which were bolted. The bolts are removed by a helper, working behind him.

The mineral production of Peru for 1912 is contained in the Boletin del Cuerpo de Ingenieros de Minas de Peru, No. 80, 1914, as follows:

Peruvian Mineral Output, 1912.

Minerals	Weight unit	Weight
Coal	metric ton	278,027
Oil	metric ton	233,600
Gold	kilogram	1,435
Silver	kilogram	324,352
Copper	metric ton	26,070
Lead	metric ton	4,050
Vanadium ore	metric ton	3,048
Bismuth (fine)	kilogram	51,038
Tungsten ore	metric ton	105
Mercury	kilogram	400
Borax	metric ton	1,074
Salt	metric ton	23,202

SEWAGE DISPOSAL PROBLEM IN CHICAGO.

IN their preliminary report upon the sewage disposal problem of the City of Chicago, Dr. Geo. A. Soper, A. J. Martin and J. D. Watson, a board of experts, appointed by the harbor and river improvement committee, have cited the following to be the conditions found after a careful study of the sanitary problem of the city:

The conditions of sewage disposal which exist in the Chicago River and its outlet are conceded to be unsatisfactory, and it is the opinion of the board of experts that the disposal of the sewage cannot be made to answer the reasonable demands of sanitation without radical improvement.

It may be said that nuisances exist in various places in the contributing arms of the Chicago River, but not to a considerable extent, however, so far as the personal observations of the board of experts have extended, in the main channel from the lake to the drainage canal. Practically the entire watershed of the Chicago River is populated or soon will be built up. The drainage channel flows through open country for many miles, and its condition, although observed to be foul by those who have had occasion to visit it, does not constitute a nuisance for the reason that none are compelled to reside or work within the sphere of its offensiveness.

Vital statistics of Chicago have been compared with those of large cities whose drinking-water supplies have been filtered, and it appears to have been shown that Chicago has one of the cleanest and purest waters of any large city in America. There seems generally to have been sufficient protection afforded up to the present time. Apparently the object in placing the intakes as far out as practicable into the lake has been not only to avoid contamination along the water front but to get clear water. At times of storm the water of Lake Michigan becomes turbid near shore, clay being conspicuously present. After fresh easterly winds even the best water obtainable from the 4-mile crib becomes noticeably turbid.

On the days when the inspections of the Desplaines and Illinois Rivers were made the water was offensively polluted with sewage as far as Ottawa—85 miles from Lake Michigan. Where bridges crossed the stream it was possible to see unmistakable evidences of the sewage. Odors were noticeable, grease lay upon the surface of the river, dead fish were numerous and large quantities of sewage fungus were observable in the water. Through the whole course of the stream from Chicago to and below Ottawa gulls were seen feeding on the solid refuse which the sewage brought down.

The report contains the following opinions and recommendations:

Dilution alone cannot be relied on as a permanently satisfactory method of disposing of the sewage of the district. It offers an insufficient means of disposing of the sewage at the present time, and would prove still more inadequate in the future, in spite of the full quantity of water which the drainage channel can carry. It will ultimately be necessary to treat practically all sewage before it is discharged. The conditions which now exist are not so insanitary as to call for improvements which will involve immediate and large expenditures of money, but the preparation of comprehensive plans for sewage disposal, water supply and river development should be undertaken immediately.

It is not possible to procure a satisfactory water supply by diverting the sewage to the drainage channel and extending or altering the location of the intakes. For the protection and improvement of the supply the city should look forward to the construction of filtration works.

Some of the principles and lines on which to proceed are:

The principle of diverting the sewage from the lake should be adhered to, in spite of any degree of sewage purification or water purification which may be employed.

Full advantage should be taken of as large a volume of diluting water as may be obtainable from the lake, in order that the cost of finally disposing of the sewage may be reduced to a minimum.

It is desirable to concentrate as much of the sewage as practicable at a point beyond the built-up sections of the city and in the vicinity of the drainage channel, where the sewage can be treated sufficiently to permit the effluent to be discharged without serious danger of offense.

To avoid excessive cost and in order to relieve the drainage channel as far as practicable, it will be desirable to treat the sewage of some parts of the city in the areas in which the sewage is produced.

Practically no sewage should be discharged into the Chicago River or the drainage channel without some form of treatment, except in times of storm, when suitably located overflows will be permissible. The sewage should, for the most part, be collected by a system of intercepting sewers running along the waterfront and extending to the central disposal station.

The minimum requirement in the treatment of the sewage at the main station should be the removal of the suspended solids by screens and settling basins.

The arms of the Chicago River which have no present or future value for navigation, and which are now in a foul and stagnant condition, should be filled in.

All considerable flows of especially foul liquids, such as those from the stock yards, should receive special treatment before they are discharged into the Chicago River or the drainage channel.

The disposal of the sewage in the Calumet territory is a local problem which can and should be solved by the construction of one or more purification plants.

SEWER DISCHARGE DIAGRAM.

Last year a sewer discharge diagram prepared by J. M. M. Greig of the Sewer Department, Toronto, was published in *The Canadian Engineer*. Some reprints were made, a few of which are still to be had. The diagrams, together with the accompanying text, are each mounted on a stiff board. One of these will be sent to any reader whose request reaches us before the supply is exhausted.

A statement recently given out by Toronto authorities, announced that with the advent of spring, \$83,000,000 worth of engineering work alone would be well under way in Toronto. The Federal, Provincial and Municipal Governments, with the railways and private corporations, will spend on the development of Toronto well over \$250,000,000 during the next few years. How conservative this estimate is will appear from the following table compiled by Mr. G. H. Maitland: Harbor Board, \$24,000,000; water front viaduct and new Union Depot, \$15,500,000; additional filtration plant at Island, \$1,300,000; Bloor-Danforth viaduct, \$2,500,000; east city waterworks plant, \$6,700,000; new buildings (exclusive of those mentioned in this list) averaging at \$30,000,000 per annum for six years, \$180,000,000. The foregoing six items alone total \$230,000,000. The list does not take into account street extensions and widenings, pavements, the North Toronto depot, civic car-line extension, general maintenance, sewers—three of which sewer systems will alone cost \$7,000,-000 [illegible] no less than \$106,500,000, an increase of over 166 per cent. in four years.

HIGHWAY LEGISLATION.*

By W. A. McLean,
Provincial Commissioner of Highways for Ontario.

HIGHWAY legislation is, at the present time, prominently before the public in every province of Canada, in all of the United States, and in almost every civilized country of the world. Three-quarters of a century ago, there was much activity in the building of main roads. Had that activity continued, the older provinces of Canada would have been well equipped with roads, and the present emergency would not have existed. A long period of neglect, and the greater efficiency of the road by means of the motor car and motor truck, have united to create an urgent need for road improvement.

Legislation alone will not build roads. Laws are merely the rules of the game. They define the game and provide for fair play. But good laws are necessary to the building of roads; as necessary as is the steam engine to the moving of a train; or as essential as the dynamo to the creating of electric current. While they do not make roads, they are the machinery for assembling and directing the power that already exists. They are the means by which energy is focussed and applied. The real source of energy, the real motive power in the building of roads, is in the ideals and demands of the people.

No two countries in the world have similar road laws. However satisfactory a code may have been in one country, it would be impossible to impose it with equal success, indeed without disaster, upon another. Climate, past traditions, customs, temperament and viewpoint of the people, existing municipal and other organization, local requirements and conditions affecting traffic, must be considered, and the adjustment of correspondent legislation is a matter for delicate and skilful treatment.

While the system of one country could not be adopted by another, all experience is of value in considering the requirements of any set of conditions, and may teach us what to imitate, to modify, or to avoid. A study of measures successful in other countries will indicate, furthermore, that there are certain principles which are universally applicable and necessary to success.

Cities and Main Roads.—That cities should contribute to the cost of roads in the open country is one of the first principles which Canadians need to learn, and embody in their legislation. Prior to the initiation of railway construction, central governments, with revenues drawn from, or to be credited to cities as well as rural districts, were active in road construction, particularly main highways. These main roads were heavily travelled by long lines of wagons carrying farm produce, and stage coaches for travellers, with taverns for their entertainment at every cross-road.

In the progressive European countries their roads were built more than half a century ago, and have since been well maintained. On this continent the building of main roads was little more than commenced with the coming of the steam railway; towns and cities concluded that their interest in the common road had ceased and their financial support was withdrawn. With the ceasing of long-distance travel and transportation, toll-roads were no longer profitable for private corporations. The resident of the city for many years did not even realize the value of good pavements in front of his own home, and he said to the farmer: "The country roads are yours. They are of no concern to me. If you want to drive axle-deep in mud, do so. If yon want to fix them up, pay for them yourself."

With the coming of the bicycle and the pneumatic tire a quarter of a century ago, there was the dawn of an awakening. That has been enlarged upon by the motor vehicle. To-day the economic value of good roads not merely to the producer, but to the consumer; not merely to the farmer, but to the merchant and manufacturer, is being studied; and that every community is benefited by good country roads is again becoming a generally accepted truth. Initiated by the personal use of bicyclist and motorist, it has gathered impetus from the high cost of living, leading to the broader knowledge that the city and town are immensely benefited by the progress and development of the township. Cities are realizing that the cost of good roads is their own burden, as well as that of the farmer.

The matter is of deeper interest in Canada than in the United States, from the fact that the revenues of State Governments are drawn largely from direct taxation collected with the municipal rates, whereas in Canada, provincial revenues are derived from indirect sources, not readily expanded to meet growing needs, and direct taxation for provincial purposes is avoided. As the contribution of cities to main road construction is necessarily made through the wider authority of provincial administration, the matter is creative of difficulty.

Municipal Authority.—Local self-government through municipal organization is in the highest degree desirable in nurturing an intelligent, progressive, self-reliant people. A lively interest in their local affairs—of roads, drainage, education—creates a sense of responsibility and a knowledge of government that shows itself in the home-life and in the higher statesmanship of a people. It is my personal observation under many conditions, that the fullest responsibility for local self-government meets a ready response from all the best citizenship, and has its reward in the greater dignity of the individual and of the nation.

A central government of province or nation, therefore, should not do for the people what they can do for themselves. A central government has enough to do with its revenues in ways that local self-government cannot, without diffusing its energies upon matters which private enterprise or local organization should control.

It follows that the central administration should, within bounds of equity and magnitude, allot to municipal bodies the necessary authority to control matters within municipal scope, rather than to retain or absorb them. By giving to local authorities the means of organization, they can do much in the way of raising money, and directing the expenditure toward effective road maintenance and betterment. It is primarily the business of a central government to see that local authorities are provided with the most efficient means of organization possible, for road purposes.

Centralized Authority.—On the other hand, experience in our own and other countries has indicated that a complete system of good roads cannot be created by local organization alone. In Eastern Canada the main roads to which we have referred (though they have suffered by a long period of neglect) were opened and improved by the central governments, or were constructed by toll road companies. The same was true in the Eastern States, and in the revival of road-building there, roads are being built, or are being largely subsidized by State Governments. In the United Kingdom of Great Britain and Ireland, the existing main roads were constructed by

*Read at the First Canadian and International Good Roads Congress, Montreal, May 18th, 1914.

turnpike trusts; they later passed to counties with an Imperial subsidy for maintenance, but national influence is now being restored. In France the great system of national highways was built, and is maintained by the State; while through subsidies, the influence of the Department de Ponts et Chausseès, is extended to the Departmental and Communal roads. In Germany the roads were built as military highways by the central government.

The maintenance of main roads, as with construction, has received and is receiving the support of the central governments. In the older countries of England, France, Italy and Germany, the main roads have long since been built, and the present large expenditures of central authorities is almost entirely for maintenance; and it is for road maintenance that their finely organized engineering corps are retained. Central governments should exercise a controlling hand in the maintenance of main roads, which they have built or largely subsidized.

Road Classification.—It has been pointed out that, while municipal responsibility should be encouraged, there is a point at which, in order to obtain results, the influence of a central authority must bear directly upon road administration. A consideration of the "Classification of Roads" will assist in determining the point at which the forces of a central administration should be applied.

Roads should be built to meet the needs of traffic. For example, there are roads which, lightly travelled, by an initial expenditure of $1,000 a mile, will remain in good condition for ten years; on the other hand, there are other roads which, because of heavy traffic, demand an outlay of $1,000 per mile annually for maintenance alone. For this reason, roads admit of classification according to traffic for purposes of construction and maintenance, revenue and administration. They must be constructed and maintained adequately; revenue must, in equity, be derived from those who are benefited; and organization must be commensurate with the work.

Commonly, there are four phases to be considered with other possible subdivisions attendant upon local circumstances. These are:—

1. Interurban roads, between large cities; in general they are the main roads of a century ago, which were paralleled by steam railways.

2. Main market roads radiating from market towns and shipping points, usually at right angles to the interurban roads.

3. Local roads, or outlying feeders to the market road, but which serve only a limited area, and upon which traffic does not concentrate.

4. "Suburban roads"—the main roads adjacent to large cities, which carry an intensified form of market and other traffic, and which may be part of an interurban route. These roads usually carry the heaviest traffic of the country.

Division of Labor.—Again, gathering previous threads, we have reached the conclusion that local responsibility for roads is desirable as far as possible; that cities should contribute to the cost of roads; that the control of main roads or a directive influence upon them by central authorities, is an established principle in the creating of a complete system of good roads. With local authorities in charge of local roads, those of least cost and traffic, and central governments at the other end controlling or directing the more costly "interurban" roads it becomes a matter for special consideration in every province and country as to the intermediate point at which the "division of labor" should be made. It is too extended a matter to consider, in a short address, what has been done in the various countries in this regard, but it is perhaps of timely interest to observe the recent proposals for the Province of Ontario. These suggestions were:—

1. That township councils should provide for and control the roads of local travel, with the proviso that as a means of encouraging better methods and organization the province will grant a subsidy of 20 per cent. of their cash expenditure, for a limited period of years.

2. That county councils should provide for and control the main market roads, the province to grant a subsidy of 40 per cent. of their expenditure in construction and maintenance, the work to be under provincial regulations.

3. That all cities having a population of 10,000 or over should levy a tax of 3/4 of a mill annually on their assessment to be spent on the main market roads of a suburban area surrounding each city.

4. That the province, from the revenue derived from motor vehicles, should take the place of the cities in interurban roads (outside of suburban areas) and pay two-thirds of the cost of construction; thereafter, 40 per cent. of the cost of maintenance.

For the control of expenditure on suburban and interurban roads, it is proposed that boards of trustees be appointed, their work to be carried out under regulations and supervision of the Provincial Highway Department.

Supervision of Roads.—Clearly defined responsibility; skilled and experienced supervision of roads by municipality and government, each in its own sphere, are allied objects, which should be at all times kept in view in forming legislation. Old laws cannot be uprooted, and fully developed new laws put in their place over night. Skilled road engineers and overseers cannot be created in a day by Act of Parliament. But Acts of Parliament can, progressively, as public opinion permits, lead to the stage at which every municipality will be required to place its road construction and maintenance under the supervision of men who will be kept in office permanently so that they may acquire the skill and experience so much needed.

One of the difficulties of the day in Canada is that, in commencing and carrying on our work, we are too often compelled to put it in charge of men who are inexperienced, and who have to gain their knowledge and experience through a course of costly mistakes at the expense of the public. Schools and colleges cannot do all in turning out the class of men needed. They can do something to initiate the process of education. But the public must learn patience in a situation which only time can remedy. The matter is one which suitable legislation could greatly foster by requiring each municipality to appoint a road superintendent as permanently in office as a municipal clerk or treasurer. The countries of Europe largely owe their superior roads to the fact that, to the laborer, the repairing of roads is a permanent trade, and to the foreman and superintendent, it is a life-long occupation.

The Frontage Tax.—The frontage or area tax is from time to time suggested, and is to some extent used to provide for road construction in the open country. Care should, however, be taken in applying it to farm property. There can be no doubt that land values are advanced by the building of good roads; and that to increase the assessment on these lands causes the owner to pay only on the new values without requiring him to pay anything on capital account.

If we wish to encourage road construction, is it advisable, by levying a frontage rate, to collect the cost of the work, and at the same time place, on an increased assessment, a tax for all local purposes? It is subject to the old objection that land should be taxed for its intrinsic

value, not for the improvements on it. It is reasonable to conclude that, if the owner pays for the construction of a road past his farm, he should not be penalized by an increased assessment because of it; but, on the other hand, if the frontage tax is not applied, the natural course of an increased assessment should follow. In special cases, if a road of exceptional quality and cost is built, the owners may not feel it a hardship to pay a portion of the cost by a frontage or area levy, as well as their tax on an increased assessment.

In coming to that conclusion, we have considered farm property only. The owner wishes the road past his farm because he wants to live on it. He does not wish to sell. Apart from improved market facilities, the farm is no more fertile or productive. That is the general rural condition.

But adjacent to large centres of population, good roads have another effect. Lands reached by them are often changed in character. From purely farm purposes, they may, very often do, obtain a new value for residential lots, factory sites, or market garden plots. When an expensively built road gives lands a new commercial value beyond that of farm property, permitting the owner to sell for fancy prices at a large profit, the payment of a local improvement tax on a frontage or area basis, is just and entirely practicable in application.

Motor Vehicle Fees.—An emergency exists to-day in the road situation in every country, particularly on this continent. If we need good roads to-day the work should have been commenced fifteen years ago. If we will need a system of good roads fifteen years hence, we should begin construction now. To carry on the work, governments urgently require increased revenues for a large outlay is necessary. Everywhere the motor vehicle, for which the best roads are now being urged, is recognized as a proper object of taxation. They are commonly owned by men of means, they do serious injury to the roads, and their value to the owner is largely increased by the extension of good roads, so that he can travel over a greater area with more speed and comfort, and with reduced wear to the vehicle.

To meet the present emergency, the opinion is advanced that every owner of a motor vehicle should be willing to contribute a reasonable annual fee. As to whether the taxation of motor vehicles should continue for all time, there may be room for doubt. There is every probability that the number of motor vehicles will increase largely, and that they will become the most common user of the roads. When that stage arrives, while the imposition of a tax may be justified on a "personal property" basis, it can scarcely be continued as a penalty for injury to the road, and on that score should become as obsolete as the toll road.

General Highway Legislation.—Highway legislation of a varied kind is, in all countries, steadily increasing in volume. With laws, as with trees, there is need for constantly pruning old and dead wood, in order that the new growth may be encouraged and provided for. Unfortunately, some of the dead wood, such as statute labor, is difficult to remove, and remains a hindrance to more efficient measures. Necessary highway laws, of all countries, are largely typified by those of Ontario; the more important of which are:—

1. The highway sections of the Municipal Act, defining the powers and duties of municipal councils relating to highways.
2. The Local Improvement Act, providing for what is commonly known as the frontage system.
3. The Act respecting statute labor.
4. The Highway Improvement Act, making provision for provincial subsidies to main roads.
5. The Colonization Road Act, providing for roads in the northern and sparsely settled portions of the province.
6. The Highway Travel Act, enumerating what may be termed the "Rules of the Road."
7. The Motor Vehicles Act, containing provisions governing the use of motors on the highway.
8. Miscellaneous Acts relating to snow roads, toll roads, toll exemptions, snow fences, traction engines and tree planting.

While there are many phases and details of highway legislation, the immediate need is to make adequate arrangement for construction and subsequent maintenance. Laws toward this end should be just as regards taxation; the division of responsibility should be well considered; there should be ample provision for skilled and experienced control; methods of organization should be simple in their application. With fair play assured, the citizens of Canada may be depended upon to enter into earnest cooperation.

NEED OF ROAD CONSTRUCTION AND MACHINERY IN DOMINICA.

It is stated that Dominica is likely to undertake soon an extensive scheme of road construction, and that an opportunity for business for manufacturers of road machinery is consequently afforded. At present the island has not a single good road and many sections of it are entirely without transportation facilities. Owing to the extensive cultivation of limes and the high prices obtained for them the owners of some of the large estates are becoming wealthy and even the peasant proprietors are very prosperous, but many of the estates are very badly in need of roads to carry their products to market.

The British Secretary of State is strongly urging the adoption of a comprehensive scheme of road construction, and the general sentiment of the taxpayers in the island being strongly in favor of such a programme it is almost certain to be undertaken in the near future. At present all road work is done by hand and even for the improvement and maintenance of roads already established it would be economical to use road-making machinery. As an illustration of the need of roads in some sections of the island, it is stated that in one district where at least $300,000 have been expended during the last 12 years in the development of lime estates, most of which are just coming into bearing, the cost of transporting fruit and lime juice is so prohibitory that it may be necessary to allow limes to rot on the ground although at present prices they would make fortunes for the estate owners if they could be got to market. It is stated that in this district the cost of carrying a cask of lime juice to Roseau, the shipping point, is from nineteen shillings to twenty-one shillings.

Canadian manufacturers of road machinery who think of supplying the requirements of Dominica should note that it is a land of hills and valleys, that most of the hillsides are fertile and suitable for cultivation or for growing limes, cocoa, coffee and oranges at quite high elevations and that it will consequently be necessary to construct roads on hillsides as well as in the valleys. The general opinion seems to be that the roads should have easy grades and be suitable for motor cars. At present most of the roads are only bridle paths and not very good bridle paths although they are used by horses, mules and donkeys.

The firm of Messrs. Wettlaufer Brothers of Toronto, have opened a branch of their general engineering and manufacturing business at [illegible] Dewdney Avenue, Regina, Sask.

The Canada West Grain Company of Melfort, Sask., has opened an office at Winnipeg, Man. It is the intention of the company to build several new elevators this summer and to purchase several others.

Editorials

INDEXING TECHNICAL ARTICLES.

Beginning with this issue, *The Canadian Engineer* will endeavor to provide weekly a convenient and adequate means whereby its readers may establish for themselves a card index of the articles of special interest to them in their work. Little originality is claimed for the new departure as it has been tried in one way or another by several other prominent engineering journals, with a fair amount of success. Obviously readers have frequent occasion to refer to articles that have previously appeared in these columns, and unless such opportunities are taken advantage of in the investigation of a problem at hand, a full measure of benefit is not being derived from the store of information there available.

The page immediately inside the front cover of each issue has been reserved for this purpose. On this page will appear an index and synoptical reference to the more important articles which that issue contains. It will convey at a glance an idea of the scope of each article, its approximate length, its title, its outstanding features and the page upon which it begins. This information will be arranged concisely and in such a way that an engineer may select those articles that may be of general or particular interest to him in his work, and mount them individually on ordinary blank cards. It only remains to file each succeeding set, as issue after issue comes to hand, each reference under its proper heading, such as bridges, sewage disposal, road construction, etc. Then, when a future occasion arises, in which he desires to look up articles on a special subject, he has only to refer to his card index system, which will at once place him in possession of a list of all the articles that have appeared during the period of time over which his index extends. He may see at a glance what each one covers and the page upon which each is to be found.

Undoubtedly the system will prove a time saver in any office or library and will enhance the value to the reader of the journal itself in providing a readily referred-to index covering what has been published since the last semi-annual index was issued, and in classifying articles to suit the needs of each and every reader.

PROGRESS OF THE CITY-PLANNING MOVEMENT.

The 6th National Conference on City Planning, held in Toronto May 25th, 26th and 27th, was a clear indication that the movement toward an intelligent and scientific treatment of the growth of our towns and cities has many evidences of encouraging progress. That the Conference was attended by delegates from 74 cities and towns and had associated with it exhibits from no less than 31 Canadian cities and towns, indicates also that it is being recognized in an approving way. Fortunately, the ideas entertained for some time by the public in general and, in the earlier stages of the movement, by some of its most consistent advocates, viz., that city-planning would deal with the general physical transformation of cities, particularly the congested central and business portions, is becoming overcome. People are realizing more and more that the city-planning movement has to deal primarily with the growth of a community, with only such changes in the old established sections as are necessary for the health and convenience of its populace.

The addresses and papers presented at the Toronto Convention clearly emphasized the degree of reformation which might be expected to follow an application of modern science and knowledge in the expansion of our cities. The need of such application is always with us. The knowledge itself is not new, as a general rule, but the various city officials possessing it, when organized into co-operative bodies, are able to confine their ideas and to impress the citizens, particularly those who have to do with the growth of the city, with the logical importance of planning in advance of that growth. Those of our Canadian cities which have already adopted the idea in an official way are making encouraging progress, while others are beginning to show signs of activity.

The draft of a city planning act which was prepared by a committee on town-planning and housing legislation appointed by the Commission of Conservation, Canada, and which was presented for discussion during the Conference, incited a widerspread interest throughout the country than that which would have naturally resulted from the meeting. This art deals with the establishment of a town-planning board in each of the various provinces. In addition each municipality may create for itself its own housing and town-planning board, or the central board may authorize the establishment of such a local board to prepare a town-planning scheme under the direction of the former. The act covers a number of questions contingent upon the movement, such as taxation, compensation, etc. It came in for a considerable amount of discussion at the Convention, and many suggestions were brought up in connection with it.

Undoubtedly one effect of the Conference and its proceedings will be an agitation throughout the various cities of the Dominion for a measure and an organization which will have for its aim a more intelligent and comprehensive direction of the growth of the cities and their various departments than has been known heretofore.

ROAD CONSTRUCTION IN NORTHERN ONTARIO.

From the report of Mr. J. F. Whitson, road commissioner, it is ascertained that 764 miles of roads were constructed, or partly constructed, and improved in Northern Ontario during the season of 1913. Of the total mileage 500 miles were graded, part of the macadam road being macadamized or resurfaced. About 280 miles of the total were cut through forest.

During the season of 1912 a good deal of work had consisted in cutting out new roads which, owing to the wet season, it was found impossible to burn off. Last year all these roads were burned off and many of them graded and ditched.

In the older sections the trunk roads, which often followed the ridges, and which were in many instances crooked and unsatisfactory as to grades and drainage, were straightened out, grades modified, and special attention given to drainage, old culverts being replaced by permanent ones of stone, corrugated iron pipe, etc.

The sum of $1,081,172.28 was expended during 1913 on the construction of roads in the northern section of the province, thus making a total expenditure at the end of 1913 of $1,274,255.08 out of the $5,000,000 loaned for this purpose.

WASH BORING FOR THE WINNIPEG-SHOAL LAKE AQUEDUCT

OPERATIONS DURING SEVERE WINTER WEATHER AT INTAKE SITE AND FALCON RIVER CROSSING—DATA CONCERNING COSTS OF EQUIPMENT AND OPERATION—METHOD OF SINKING THE TEST HOLES.

DOUGLAS L. McLEAN
Of the Greater Winnipeg Water District's Field Staff.

IN connection with the extensive field investigations undertaken by the Greater Winnipeg Water District and pushed forward under the direction of W. G. Chace, chief engineer, from November, 1913, to March, 1914, for the location of the aqueduct line and appurtenant works from an intake site at Shoal Lake to the City of Winnipeg,* considerable subsurface boring and test pit work was carried out. At Indian Bay, Shoal Lake, Party No. 3, of which the writer had charge, made a number of wash borings at the intake site and Falcon River crossing. Mr. R. T. Sailman, B.Sc., who had considerable experience on deep drill work in New York State, was detailed from head office to assist on this work, as well as to look after the entire underground explorations along the line to Winnipeg.

Fig. 1.—General View of Outfit. Fig. 2.—"Drilling." Fig. 4.—Jacks, used only to raise casing after drive weight has been in operation.

The work at Indian Bay was carried on under the severe climatic conditions of a Canadian winter, with a "string of tools" which, though complete for the purpose, was not as elaborate as that necessary for deep drilling. The following list of equipment with cost of same may be useful for reference when similar work in contemplated:

*Described in *The Canadian Engineer*, Vol. 25, pp. 605-[illegible] [illegible]rd, 1913).

TABLE I.—LIST AND COST OF EQUIPMENT.

Quantity.	Description.	Unit Price. $ c.	Cost.† $ c.
50 feet	2½" Extra heavy pipe (drive casing) in 5'-0" lengths, at....	.57	28.50
	Cutting and threading pipe...	....	5.00
50 feet ...	1¼" Extra heavy pipe—five 4'-0" lengths and six 5'-0" lengths, at	.25	12.50
	Cutting and threading pipe...	...	3.30
10 only....	2½" couplings, at	.16	1.60
11 only....	1¼" couplings, at	.08	.88
1 only ...	Malleable 1¼" tee, at	.16	.16
1 only.	Double run 10" wooden block, at	1.85	1.85
60 feet	¾" Manilla rope, at	.14 lb.	1.40

†At Ingolf Station, Ont.

Quantity.	Description.	Unit Price. $ c.	Cost.† $ c.
1 only	Hand force pump No. R. 470—30 gallons per minute, at	7.00	7.00
2 only	24" Stillson wrenches at	2.25	4.50
15 feet	1½" discharge hose at	[illegible]	4.50
20 feet	2" suction hose at	.35	7.00
1 only	1¼" street elbow at	.15	.15
1 only	1½" coupling for hose at	.30	.30
1 only	2" x 1½" bushing at	.10	.10
1 only	1½" short nipple at	.10	.10
1 only	1½" x 2" nipple at	.10	.10
1 only	Drive weight 7" diameter x 15" long, 2" hole all the way through long dimension, widened to 3½" from 4" below top to top, 1" hole through same 2" from top, for 3' of ¼" flexible wire rope for handle at	5.60	5.60
2 only	1½" chopping bits of drill steel with 1¼" threads 8" long at	6.00	12.00
6 only	Pairs lumberman's rubbers, 2 buckles, sizes 10, 11 and 12, at	1.60	9.60
1 only	Pipe vise to take 2½" to 1¼" pipe at	2.00	2.00
1 only	2" foot valve at	.45	.45
1 only	Machinist's hammer at	1.10	1.10
2 only	Cold chisels at	.35	.70
1 pair	Jacks 2½" x 18" with handles at	6.80	13.60
	Steel spindles for same at	.10 per lb.	1.20
2 only	Sleeve couplings, 1¼ W. T. at	.10	.20
3 only	Sleeve couplings, 2½ W. T. at	.16	.48
2 only	1¼" nipples 6" long at	.06	.12
2 only	1½" to 1¼" reducing couplings at	.10	.20
2 only	1½" nipples 6" long at	.08	.16
6 only	One-gallon pails at	.21	1.26
1 pint	Machine oil, black, at	.15	.15
1 only	2" nipple, 6" long, at	.10	.10
1 only	Recovering tap at	3.75	3.75
2 only	Sister hooks at	2.50	5.00
1 only	Clasps for 2½" pipe at	2.00	2.00
1 only	Hoisting plug at	1.75	1.75
6 only	Couplings for 1¼" pipe (extra) at	[illegible]	[illegible]
1 only	Ice chisel at	3.50	3.50
2 only	Axes, No. 3½, at	1.25	2.50
1 only	Air-tight heater at	2.10	2.10
1 only	Length stove pipe at	.10	.10
2 only	Chain tongs, No. 33 Vulcan, at	4.50	9.00
2 pairs	Extra leathers (front and back) for piston of Meyers low-down force pump at	.35	1.40
3 only	Logs for tripod. Delivery of outfit from C.P.R. station to site (18 miles), at		12.10
			$171.54

With this equipment, a general view of which is shown in Fig. 1, the process of sinking the test holes was very simple. It was substantially as follows:

The derrick or tripod, equipped with three logs, was set up over the station, where a hole was cut through the ice and the depth of water obtained by sounding. After this, a suitable length of casing was put down. At the same time a hole for the pump suction was made and a fire started in the water heater, in order to facilitate the thawing of the tools. Then the drill rod of required length, with chopping bit on lower end, and hoisting water-swivel on upper end connected to derrick-rope and by hose to the force-pump, was put down inside the casing. The position of the bottom of the casing and the drill rods having been noted, the drill rods were churned up and down by means of rope over a block attached to the tripod. At the same time, water was forced down the centre of these rods to an outlet in the chopping-bit, and thence up between the rods and the casing (see Fig. 2). The chopped material brought up by the water jet was noted by the leader in charge of the work.

To sink the casing, chain tongs were attached, and it was rotated, as shown in Fig. 3. This rotation or turning of the casing to keep it free from sticking to the material drilled through, was the detail that added most to the speed of work, not only in sinking the casing, but more especially in the pulling of the pipe.

This method of sinking the casing was not practical at all times and in some cases the drive weight was used to pound the casing down. After it had been used, it was necessary to use the two jacks to draw the pipe, as shown in Fig. 1. As the hole was sunk either by rotation of

Fig. 3.—Showing Method of Rotating and Sinking the Casing.

casing, or driving, constant watch was kept of the position of the bottom of the casing and the drill rods, together with careful note of the materials brought up by the water jet. For this particular piece of work at Indian Bay, it was found advantageous to use a force of one leader, or foreman, and four laborers.

The progress that can be made under winter conditions, and the cost of same, is given in Table No. 2. This gives the footage, the materials encountered, the temperatures and the labor and food costs. It should be of use for information when similar work is contemplated.

(For Table 2 See Next Page.)

MINERAL PRODUCTION IN GREAT BRITAIN.

As shown by a condensed statement issued by the Mine Inspection Bureau, the coal produced in Great Britain for the calendar year was 260,398,578 long tons in 1912, and 287,411,869 tons in 1913; an increase of 27,013,291 tons, or 10.4 per cent. The production of other minerals from mines included under the Coal Mines Act was as follows, in long tons:—

	1912.	1913
Iron ore	6,744,258	7,709,624
Iron pyrites	[illegible]	[illegible]
Clay and shale	[illegible]	[illegible]
Fireclay	2,287,719	2,585,763
Igneous rocks	268	688
Limestone	12,009	7,525
Sandstone and ganister	152,156	144,923
Oil shale	[illegible]	[illegible]
Barium compounds	[illegible]	[illegible]

The production of coal given above is practically complete, only a few thousand tons being obtained from open-pit workings classed under the Quarries Act. The output of iron ore will be increased considerably by the reports from metalliferous mines and quarries.

The number of persons employed in these mines in 1913 was: underground, 909,834; on surface, 218,056; total, 1,127,890, an increase of [illegible] over 1912.

CORROSION-RESISTING QUALITIES OF MODERN MILD STEEL vs. OLD-TIME IRON.

By A. T. Entlow.

WITH the marketing of mild steel for various uses, an idea is prevalent that the quality of a corrosion-resisting metal can be determined solely by a chemical analysis showing the percentage of of carbon, sulphate, phosphorus, silicon and manganese present in its composition. While such a standard of selection is to some extent reliable, this basis of determination alone may, and possibly will, lead to many disappointments and unsatisfactory results if adhered to.

While the analysis of a rust-resisting material, showing only to what extent these chemicals enter into its composition, may bear strongly on their ability to resist corrosive influences, it has not as yet been fully or even satisfactorily demonstrated that such a guide can be taken as absolute. Too many other factors enter into the manufacture of such materials, when made through modern processes, to allow of their being disregarded. That this is true will readily be seen by a comparison of modern and early methods and raw materials such as existed when the old-time lasting irons were made.

The idea that the analysis tells the whole story has its origin in the statement so often reiterated when the idea of a modern rust-resisting metal was first conceived several years ago, that "the purer the material as regards the absence of foreign chemical elements, the better would it withstand corrosion." At best this statement only conveys part of the truth.

It might be well, while on the subject, to correct another erroneous idea in connection with the quality of old-time iron, which, if followed in the selection of modern rust-resisting metals, may also lead to trouble. This is the fallacy, that all old-time irons were highly resistant to corrosion. There can be no question that in early days some irons were produced which withstood the ravages of corrosion to a phenomenal degree. This is conclusively proven by many instances of irons, hundreds of years old, still in existence, and by others in a good state of preservation after continuous service in and on buildings for fifty or more years; but because of these specimens, it should not be concluded that all old-time irons were equally good. This is not the case, the samples still extant being merely the survival of the fittest.

While the amount of the foreign elements, carbon, sulphur, phosphorus, manganese, and silicon, in modern rust-resisting metal do have considerable influence on the quality of such a material, no one can say as yet to what extent even a considerable variation in the total amount of these elements, below a certain point, or their relationship one to another, bears to corrosion resistance. This is especially true in the face of such analysis of the old-time irons as did withstand corrosive influences, and which analysis is procurable and on record.

It is impossible to find to-day record of any analysis of these early irons, which compare, even favorably, with the analysis of a good grade of modern mild steel as regards to the low total content of these impurities—and these steels are essentially irons. Yet there is no argument that these old-time irons, so far as corrosion resistance goes, were by far superior to any of the mild steel or irons, made within the last quarter century, at least.

That one material may contain but 4-, 5- or 6-hundredths of one per cent. of these impurities, and another 8-, 9- or 10-hundredths of one per cent. of the same impurities, may not, therefore, prove much of anything. On the other hand, such an analysis of a modern metal, showing that it has been so highly purified, may actually demonstrate just the opposite to corrosion resistance, inasmuch as the vigorous treatment to which the modern metal must have been subjected to so eliminate or free it from these impurities, may have so destroyed its life or vitality that it will not have the power to stand up under the incessant strain of corrosive influences. Further, treatment which is sufficiently vigorous to accomplish such results may actually, and undoubtedly does, add or introduce elements or conditions to the metal which are just as deleterious as the elements which it removes.

The early irons and their manufacturer offer two sources of information on these points on which to base some conclusions as regards the value of analysis as applied to modern-made rust-resisting products. One of these is the quality of the ore, the other the processes by which they were made. Did the good grades of old-time iron get their quality of rust resistance from the ore itself, retaining it through all the different stages of refinement through which it passed from ore to finished product, or was this quality given the finished product by reason of the processes through which the raw materials passed in the course of conversion, regardless of the quality of the raw material?

It has been stated on good authority that the ores from which the best quality of the irons were made, contained a very marked amount of vanadium, the presence of which in the ore was largely responsible for their wonderful qualities. There seems to be no good reason to doubt that this was so, because of the known effects of vanadium as used to-day in connection with the making of some grades of high quality steels. When added to steel, vanadium overcomes the detrimental effects of gases, also adding "vitality" or "life" to the steel. We are further told on good authority that it was not uncommon, in the ores from which these irons were made, to find the phosphorus and sulphur not exceeding .002 respectively. It would seem, therefore, that the high quality of these particularly old irons was due largely, if not entirely, to the high quality of the raw material from which they were made.

The contention or belief, of many, that the corrosion resistance of these irons, in fact of any iron, was due to the presence of slag and cinder in the iron is hardly tenable; otherwise the manufacturer would hardly have worked and re-worked his iron with the avowed intention of getting rid of the slag and cinder to as great a degree as possible. Old-time iron contained slag and cinder because the manufacturer could not entirely eliminate it—not that he wanted it there. Iron is improved by working for this very reason—it rids itself of the slag—and for this selfsame reason such iron commands a higher price than iron which is not so thoroughly worked and contains more cinder.

All these points give a sound insight into the quality of the early raw materials, and point strongly to the supposition that it was from this source that the early irons, when they possessed quality, got it. This is further substantiated when the processes by which these irons were made is taken into consideration.

The Catalan, puddling or other furnaces, in early use, were all limited as regards their effectiveness in removing foreign chemical elements, when compared with the modern high-powered furnaces. With these early furnaces it was impossible to generate a heat of sufficient intensity, or to maintain such a heat for a sufficiently long

period of time, to do more than bring the charge of raw material to a soft or pasty condition sufficient to allow of its being worked. To remove or eliminate most, if not all chemical impurities as found in modern ores, it is necessary to generate a heat sufficiently powerful to reduce the raw materials to a liquid condition of extremely high temperature and to keep it in that state for a considerable period of time. It would, therefore, seem that the furnaces of those early times had little bearing on the subject. What effect they did have was negative rather than positive in that they were not sufficiently powerful to do much eliminating, nor were they powerful enough to produce any detrimental influence on the iron during its purification. It would, therefore, seem that the quality of the old-time iron was due to a condition of favorable circumstances rather than to furnace practice or manipulation. On the other hand, it will be seen that with the modern high-powered furnaces, and modern raw materials carrying high percentage of foreign chemical elements, to produce a high-grade rust-resisting material the question is one of process and metallurgy; and hence the risk of forming an opinion of the quality of a metal on a chemical analysis that only tells part of the story.

Having had the high-grade raw materials with which to work, it was not necessary to subject them to any severe furnace treatment thereby destroying the vitality of their product or injecting into them gases or other elements of a detrimental character.

The fuel used in these furnaces is often given credit for the superior quality of these irons, but this idea is largely erroneous. Charcoal, the fuel used exclusively in the early years of iron making, had little or no bearing on the subject, only inasmuch as this fuel being extremely pure and free from sulphur or other detrimental elements, the iron in the course of refining or while in contact with the fire, could not absorb any additional injurious chemical element to its detriment from the fuel employed.

Comparing modern furnace practice and modern raw materials which are high in carbon, sulphur, phosphorus, silicon and manganese, it is evident that the manufacturer who undertakes to produce even as good an analysis as was found in the early lasting irons, must subject his raw materials to a far more vigorous treatment, and in so doing the product must be affected in some way. That this is true is conclusively proven by the quality of the mild steel or irons produced since the introduction of the high-powered Bessemer and open hearth furnaces, notwithstanding the fact that the products of these furnaces show a better analysis, as regards purity, than the early irons.

So far as chemical analysis goes, the one striking difference between old-time iron and modern mild steel lies in the difference in the amount of manganese and sulphur present, particularly the former. The presence of greater quantities of these two elements in the one metal and the smaller amount in the other, undoubtedly has considerable to do with the difference in their corrosion resisting qualities.

It is true that, due to the absence of carbon, sulphur, phosphorus, silicon and manganese, or their elimination to the lowest possible degree, the evil of segregation is guarded against, and segregation from any cause, as proven by recent research, bears strongly on the question of corrosion, if it is not the whole cause of this evil.

Segregation in the metal produces differences of potential, and corrosion is merely the passing of the metal into solution, through electrolysis. Differences of potential may occur through elements or conditions other than by the presence of carbon, sulphur, phosphorus, silicon and manganese and may be introduced into the metal both during and after the process of purification. The fact has been pretty well demonstrated that it is very probable in reducing these foreign chemical elements to an extreme degree in order to overcome segregation, this very thing happens. It is also more than probable that in so reducing these impurities, due to the vigorous treatment necessary to accomplish this result, the vitality of the metal is destroyed, and though the material may show a phenomenal analysis, so far as the chemical impurities are concerned, it will be lacking in the necessary vitality to withstand the constant and incessant attack of corrosive influences. This further goes to show what may happen when selection is made by chemical analysis alone, so far as modern products are concerned.

The difference between ancient and modern processes, in that the one affects the metal by injecting detrimental elements during the process of refinement, while the other did not, is fully demonstrated by comparison of both practices. That this is so is fully demonstrated, if in no other way, by the fact that quite large quantities of manganese are added to the metal in both Bessemer and open hearth practice for practically no other purpose than to eliminate the oxygen absorbed by the metal, during the process of refining while in the furnace. This, by the way, is the exact time or point at which iron ceases to be iron and becomes steel—when the manganese is added. The addition of manganese or any other foreign chemical or mineral was never resorted to in the making of old-time iron by the early processes, such treatment being entirely unnecessary to make it commercially useful.

Unfortunately, while manganese is an excellent material with which to get rid of the undesirable oxygen, it is in itself most objectionable, in that it is to a large extent, if not wholly, at the bottom of the corrosion trouble, so far as foreign elements are concerned. This is borne out by the fact that high-grade early iron carried little more than a trace of manganese, while modern mild steel contains anywhere from one-fifth to one-half of one per cent. of it.

Apart from the question of how much or how little the effects of foreign chemical elements are on the question of corrosion resistance, the physical qualities unquestionably have very much to do with this question, if reliance can be placed on the physical properties of such of those old-time irons as have proven their worth after many years of service.

The density of these old irons seems to have entered into the question of their corrosion-resistance, inasmuch as the specific gravity of these irons ran as high as 8 and sometimes over, while that of modern mild steel is given as 7.85, though it is doubtful if it will generally run this high. In other words, a cubic foot of old-time iron would weigh on this basis, 500 pounds or more, while the weight of a cubic foot of mild steel would weigh about 490 lbs. This would indicate an entirely different physical structure in regard to the number and size of the crystals forming these two metals.

Another striking difference between these ancient and modern metals is shown in their fracture. When broken, the iron showed itself decidedly fibrous at the fracture point, while the steel at the point of breaking is decidedly crystalline. This shows that the crystals of the iron were held together so tenaciously by a force which may well be called "vitality" that before they would separate or give way, they drew out into fibres or strings, while the steel fails before the crystals are in any way deformed. This would indicate that, though the steel is a purer metal, the effect of the process by which it was made has been to

destroy in some way, mechanically or chemically, the "vitality" of the steel, which may be, and in all likelihood is, the very quality necessary in either steel or iron to enable it to withstand successfully the attack of corrosive elements.

Through the findings of investigators which, if correct, and there is no good reason to doubt but what they are, we are informed that steel made from the high-grade old-time irons stands a much better dynamic or vibratory test than modern-made steels, except some special steels such as made from vanadium. This further emphasizes the fact of the superior "vitality" of the old irons. Further, there is every reason to believe that these irons themselves would stand a like test to a far better advantage than modern mild steels which have proven so susceptible to corrosion. This lack of "vitality" may be due to the presence of the greater amount of gases in the modern steel which are decidedly detrimental to metal. It is, therefore, safe to say that the longer raw materials are subjected to the influence of the modern high-power refining furnaces to reduce or eliminate the high percentage of foreign chemical elements in them, the richer will the purified metal be in gases detrimental to quality. In other words, as the impurities are reduced, the gases are increased and in modern mild steel making it is on this account that manganese, which is itself highly susceptible to corrosion, is employed.

Physical structure due to working, forming, reheating and cooling, must also not be overlooked in connection with this question of corrosion. Much depends on the handling of the metal while being transformed into finished products. Investigations all prove that any mechanical treatment which sets up uneven strains within the metal will induce corrosion. Improper heating, sudden cooling or working the metal at a wrong temperature produces this result and so induces corrosion even in a pure homogeneous metal. The crystalline formation of any metal, iron or steel, has much to do with its ability to withstand corrosion. The smaller and more regular and closely knit the crystals the better will the metal resist disintegration. Hard or soft spots due to improper distribution of carbon, or to any other cause, also invites corrosion. Anything that destroys the natural crystalline formation of the material or breaks down the crystals has a like effect. Iron or steel reduced too rapidly in rolling or worked at too low a temperature will have its crystalline formation upset or destroyed. Straining metals in this or other ways tends to make them more porous, which is another condition which invites rapid corrosion. The crystals in a properly made iron or steel, lie in the direction of the heat waves, passing out of the metal during cooling, and any treatment that in any way interferes permanently or destroys the natural formation or relationship of the crystals one to another, tends also to the destruction of the metal by corrosion. Compare the modern forced methods of to-day, whose tendencies are to introduce into the metal so many causes of corrosion, both in the furnace and mill practice, with the slow deliberate and careful methods of handling in the days of the early iron making practice and it is readily seen that any analysis which gives only the amount of carbon, sulphur, phosphorus, silicon and manganese present may prove very misleading and disastrous when used as a basis on which to judge its corrosion-resisting qualities.

From the foregoing it will readily be seen that in connection with a rust-resisting metal made under modern conditions, a chemical analysis of the carbon, sulphur, phosphorus, silicon and manganese may mean much or little. While such a material may have corrosion-resisting qualities as well as a very low content of these chemical elements, it is quite possible for it to give such an analysis and yet be anything but a high-grade rust-resisting material.

It is in this respect that a metal may excel, in that while its analysis may be lower, all things being considered, than other analyses, this analysis is not attained at the sacrifice of vitality or other qualities essential to any metal which is to show rust-resisting qualities equal to those of the early irons which were rust-resisting.

Both in the furnace practice and in the mill practice, absolute care must be taken that no detrimental elements accompanying the refining process remain in the metal. In the mill practice, the metal should be handled with extreme care and attention in the heating, rolling, cooling, and other processes through which it passes while being made up into the finished product. In consequence, the physical structure of the metal is not likely to be permanently destroyed, and by careful and intelligent heat treatment, any strains or other defects are eliminated which may possibly have appeared in the metal, homogeneous as regards chemical elements—practically free from detrimental gases and physical or mechanical strains—without sacrificing that element of vitality which is essential to any metal that is to be subjected to the severe corrosion-producing conditions of modern times.

TIMBER AND FERRO-CONCRETE PILES PATENTED.

A combined pile of timber and ferro-concrete has been patented by an Austrian engineer. The main object of the patent is to utilize the timber portion in the position where it will be safe against decay, and the concrete portion where it will not be exposed to disintegration by the chemical attack of unfavorable soil or water. As timber piling is known to last indefinitely when permanently below the water line, the timber section is driven down in the ordinary way till its head is one metre above water line. Previous to driving the head is rounded and a wide steel band fixed on. The head is now lifted off and a steel tube substituted somewhat conical in a downward direction. Within this steel tube is now slipped a ring wedge, strongly made with six ribs, and this wedge is driven into the head of the pile, thereby forcing the timber to spread and take the form of a cone fitting tightly the conical inside of the steel tube. The head of the wooden pile and the steel tube are thus firmly compressed together, after which both can be driven, by using a suitable head piece for the tube, to any further desired depth. Reinforcement may now be placed within the tube and concrete filled in, completing the joint and the concrete pile. In a combined pile of this sort the whole of the driving can be done with the ordinary [illegible] for timber piles, and the difficulty of placing ferro-concrete piles in boggy or marshy land is obviated. Where great length of piling is necessary this construction has been proved to have many advantages.

The Penn Iron Mining [illegible] a good grade of square braided hemp packing after experimenting with [illegible] packing for high pressure, 8-stage centrifugal pumps. [illegible] the stuffing box [illegible] the full pressure occurs, in this case, 522 lbs. Since the shaft has [illegible] longitudinal, there is nothing to distribute the pressure [illegible] packing to the other [illegible] up. Consequently, the outside ring is likely to be pressed too tight and wear a groove in either the shaft or the protecting sleeve on the shaft. No attempt is made to lubricate the packing, the [illegible] stuffing [illegible] two hours.

NOTES OF A HYDROGRAPHIC-TOPOGRAPHIC SURVEY.

By J. A. Macdonald, Hermanville, P.E.I.

THE following notes pertain to a survey which the writer made on the shores of the Gulf of St. Lawrence, on the north coast of Prince Edward Island, and which is indicated in Fig. 1. On such a survey, being a combination of hydrographic and topographic work, a surveyor finds it advantageous to have his party consist of about four men, in addition to himself. It is often found best to employ men for the hydrographic work who live in the locality and are, therefore, familiar with the management of boats, etc. There is little advantage in employing men with considerable previous experience except, perhaps, in the case of the recorder. Frequently the surveyor himself acts as recorder. Generally, one man can adequately look after this work. Then the chief requires two to act as rod men, while the principal assistant should be able to take observations simultaneously with the chief surveyor.

The equipment should include a sextant together with a transit or two compasses. The transit should be supplied with stadia hairs, as stadia readings will greatly facilitate the work. A stadia rod, or ordinary level rod, [illegible] or tape will also be found useful. The other equipment, such as buoys, sounding rods and lines, boats, range poles, etc., will depend largely on the work to be performed.

Making the Survey.—The fixed points of reference for the survey are usually located on shore, but sometimes buoys are anchored off the shore and used for this purpose. All such points should be accurately located from some measured base whose azimuth has been found. The traversing work for the location of the fixed points of reference differs in no sense from that of a topographical survey, for such a survey is usually connected with a topographical survey of the adjacent shores or banks, the triangulation scheme serving both purposes.

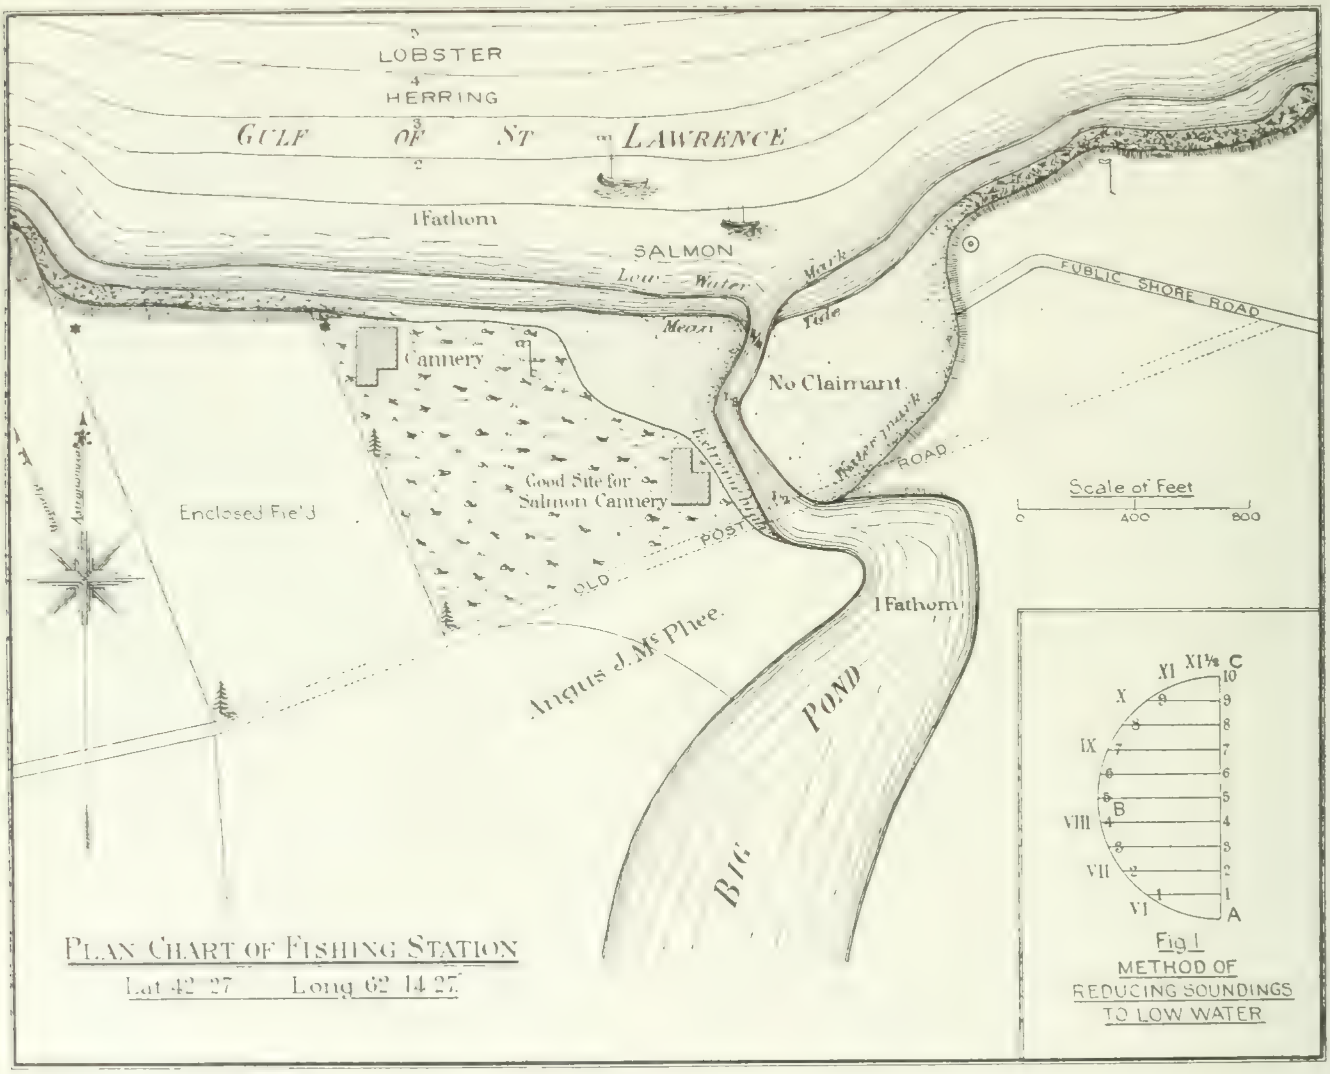

Fig. 1.

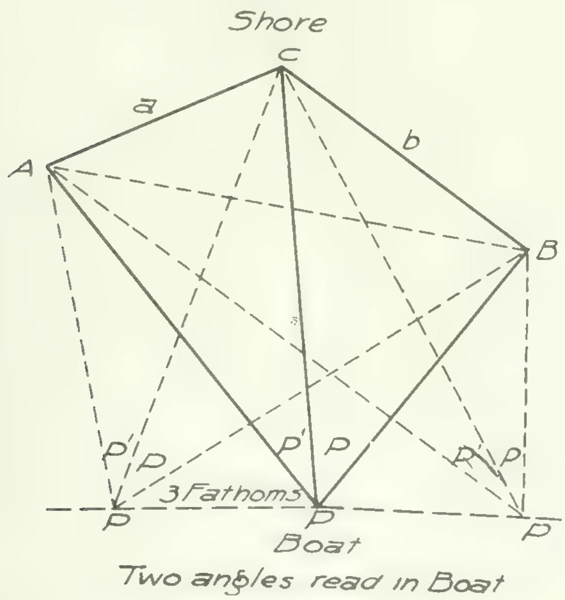
A complete traverse is first made of the shore lines at the various stages of the tide. The defining of the tide lines for plotting may involve the work being postponed for several days or weeks. It is important to get the mean tide marks. This is sometimes difficult, and one will need to watch the changes of the moon's phases. Soundings are taken by some surveyors at low tide, but it is now more common with hydrographic surveyors to take the soundings at mean tide. Close observation is needed to get the lines of low tide. High tide need not be looked for, as the high-water mark can be readily determined by the markings on the land, and a traverse made along the lines of those marks will determine its location. The banks will also have to be accurately tra-

versed. All roads, public and private, used or unused, need to be traversed and accurately plotted on the plan or chart. All farm lines and fences are to be measured and shown in their true position. The declination of the magnetic meridian should also be plotted. All of these are shown in the plan herewith (Fig. 1).



$$PAC = \text{Cot} R \left(\frac{a \text{ Sin } P'}{b \text{ Sin} P \text{ Cos} R} + 1 \right)$$

$$\text{when } R = 360 - (P + P' + C)$$

Fig. 2.

Methods.—The location of soundings can be found with reference to visible known points by two angles read at fixed points on shore, as in Fig. 3; or by two angles read in the boat with a sextant (Fig. 2). These are the two principal methods used in work of this kind. Supplementary methods of various kinds are usually brought into use, such as (1) by taking the soundings on a certain range and reading one angle either on shore or in the boat, or by both; (2) by sounding along a known range, or line, taking the soundings at known intervals of time; (3) by taking the soundings at the intersections of fixed range lines; or, (4) by means of chords or lines stretched between fixed points. These methods are variously adapted to different conditions.

Two angles read in the boat to three points on shore whose relative positions (see Fig. 2) are known. This is called the 3-point problem. Let A, C, and B be the three points on the shore defined by the two distances a and b and the angle C. Let the two angles P and P′ be measured at the point P. The problem is to find the distance AP and BP.

The angles are read in the boat with a sextant. There are several methods of solution of this problem, e.g., analytical, geometrical, mechanical and graphical solutions. The latter will only be dealt with here, though the formula for the analytical solution is given in the figure.

The angle may be laid off on tracing paper or tracing linen by lines of indefinite length, and this laid upon the plot and shifted in position until the three radial lines coincide with the three stations, when their intersection marks the point of observation. This is the most ready method of plotting such observations when no three-armed protractor is at hand.

This method has many advantages. In the first place, only one observer is required; there is no time lost in changing stations, and there cannot be any misunderstanding in the work. A large number of points, P, can be taken with the three-station points, A, B and C, on shore. The contour, or fathom-lines, 1, 2, 3 and 4, can all be taken, in a great many cases, in three or more positions, to or from the three points on shore. It is well to check the graphical solutions now and again by the trigonometrical method of solution.

Two Angles Read on Shore.—If two instruments, transits or compasses, be placed at two known points on shore, as A and B, Fig. 3, and the angles subtended by some other fixed point and the boat be read by both instruments when soundings are taken, the intersection of the two pointings to the boat, when plotted on the chart containing the points of observation duly plotted, will be the plotted position of the sounding. This method requires two observers. When there are long lines of offshore soundings to be made, and no fixed point on shore of sufficient distinctness to be observed with the sextant from the boat, this method must necessarily be used. The instruments should both be pointing to zero previous to taking an observation. Ordinary surveyors' compasses answer for this work quite well, though the transit is certainly the more accurate.

A triangulation system along a rocky shore or coast may consist of one line of stations or poles on shore and a corresponding line of buoys. The angles are read only from the shore stations, two angles in each triangle being observed. Good results are obtainable from this method if the weather is calm. If the length of any line in this system is known the rest can be determined by the ordinary methods of plane trigonometry.

Soundings on Fixed Cross-sections in Rivers.—The methods described are only usually adapted to sea soundings, and are not adaptable to river soundings. In the chart (Fig. 1) a river is shown, depths or soundings, accurate direction of flow and outline of banks given. Manifestly a different operation was found necessary for obtaining the river soundings, as well as its slope. In

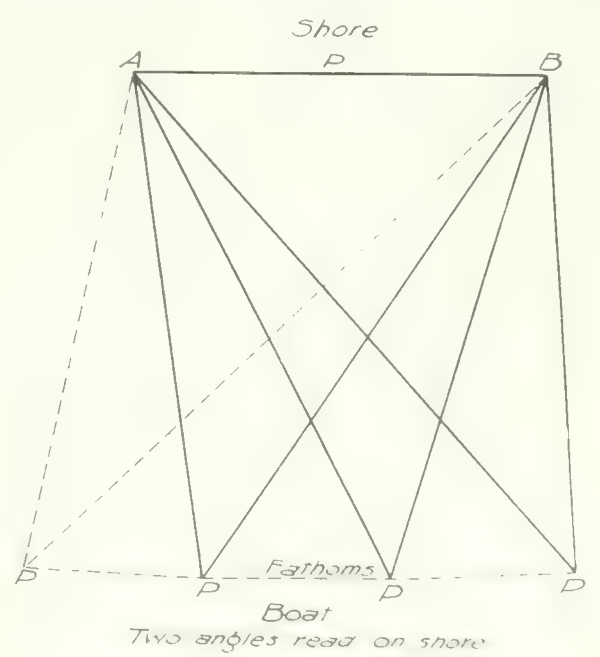


Fig. 3.

this case it is found best where the same section is to be sounded a great many times and where it is desirable to obtain the successive soundings at close juxtaposition, to fix range posts on both sides of the river, and then one or more series of intersecting ranges at points some distance below or above the section on one or both sides of the river. The soundings can be made at the same points continuously without having to observe any angles. Such a system is shown in Fig. 4. AA and BB are range poles on the section line across the river. O and O' are poles set at convenient points on opposite sides of the river, both above as well as below the section when found necessary. The poles OO' should be distinguishable by small flags. Shorter posts are set near the bank at points 1, 2, 3, etc., in such positions that the intersections of the lines O-1, O-2, O-3, etc., with the section range BB will locate the soundings at the various points of the cross-section line AA, BB. This method is very simple and effective. It is plain that by changing the position of the poles OO' several cross-sections can be taken at different points on the river without changing the position of the posts, 1, 2, 3, 4, 5, 6, 7, 8, or the base AB.

Making the Soundings.—The weight of a sounding lead will depend largely on the tide or current. A lead of 5 lbs. answers for still or shallow water, though for deep running stream, or very strong tides, a weight of 20 lbs. may be required. The line should be of a size suited to the weight, and may be composed of ordinary hemp or manilla. The line should first be well stretched for a couple of days, so as to be freed from all kinks. It is quite possible to stretch a line too much, as they are apt to shorten by use when over-stretched. Soundings at sea are always taken in fathoms (6 feet). On the United States lake surveys it is the general practice to indicate all depths over 24 feet in fathoms, and depths under that in feet. The depths here shown are all in fathoms, as was the old custom in hydrographic work. "½" and "¼" shown in this map meaning one-half and one-fourth fathoms, or 3 feet and 1½ feet respectively. If the line is graduated in fathoms and fractions of fathoms, leather tags are fastened in the strands of the line at the fathom points, and the fractional fathoms, as ¼, ½, are indidicated by cotton or woolen strips. The line should be frequently tested.

Sounding poles are found most convenient and necessary. They should be used when the depth is less than 12 feet. A pole 15 feet long will answer for obtaining 2-fathom soundings and under. The pole may simply be graduated to feet, or, where great accuracy is required, to tenths.

In tidal water the elevation of the mean tide is the plane of reference for both the topographical and hydrographical surveys, and the state of the tide must be known with reference to the mean. The elevation of the zero being determined, with reference to mean tide water, all soundings must then be reduced before they are plotted to what they would have been if made at mean tide. This can be done graphically by Bourcher's method, as shown in Fig. 1, if necessary. This is seldom necessary, as practically all soundings are now reduced to mean tide.

Lines of Equal Depth.—These lines correspond to the ordinary contour line on land, as shown in all topographical surveys in rough and mountainous countries. To draw lines of equal depth with certainty the elevations of many more points are necessary than are needed for drawing contour lines on a railway map, for example, because the bottom cannot be viewed directly, while the ground can. Where the ground is seen to be nearly level no elevations need be taken, while for a similar region of bottom a great many soundings are required to prove that it was not irregular.

River slope is a very important part of a survey where a river is involved. Sometimes it may be desirable to determine it for a given stretch of river. In ascertaining the discharge of streams it is often found necessary to set gauges simultaneously every few minutes for several hours. But such an object was not required in this case under consideration, where, as for ordinary purposes, the river slope was determined with sufficient accuracy by simply reading the level or stadia rod at the water-surface as the survey proceeded. In all natural channels the slope is quite variable. For short distances it is frequently negligible, as the water is still and almost level, then follows for a short distance a sudden fall or rapid. Streams, particularly those emptying into the sea, are subject to material changes in local conditions. This applies also to streams flowing in friable, sandy beds. Great caution must be exercised in introducing the function of river slope into any hydraulic formulæ for natural channels.

NEW TYPE OF EMBANKMENT WALL.

THE Dominion Government has awarded a contract for four thousand square yards of a new system of armour for the protection of the dyke at Laprairie, Que., against damage from water and ice of Lake St. Louis. This contract was placed with C. Gardaix and A. C. Attendu, C.E., of the Decauville Flexible Armour of Canada, Montreal, who are the owners of the Canadian patents on the Decauville flexible armour.

This armour, which was patented in France seven years ago, is intended to take the place of concrete retaining walls for the protection of river and other embankments. The armour consists of a network of cement bricks. These bricks are held together by vertical wires, which pass through corresponding holes in the bricks. The bricks are absolutely equal in size, and measure about 10 in. in length by 3 in. in width by 5 in. in height. Each brick has two holes through which the wires pass. These wires are attached to a strong horizontal steel cable running along the bottom of the embankment, and forming the base line of the whole wall.

Each brick is curved at the ends in such a manner as to form hinges with the next bricks, so as to permit of flexibility. The wires, about one-fifth of an inch in diameter, are heavily galvanized—180 grams to the square meter. Eight wires are used per running yard of brick, thus allowing a tension of about seven thousand pounds per yard of brick. The wall is held in place by its own weight and by large stone or iron anchors which are sunk into the earth at the top of the embankment, the ends of the vertical wires having been twisted together in strands, and the strands bound around the anchor.

The bricks are made of cement and sand by presses driven by hand or motor power. A pressure of about twenty-three tons per brick is obtained. Mr. Attendu states that the resistance of the bricks against crushing is about nineteen hundred pounds per square inch. Staircases of any width desired can be placed in the wall by a special arrangement of the bricks. It is stated that the cost of the Decauville armour is from thirty to fifty per cent. less than a concrete wall of the same height, length and resistance.

RELATION OF THE TECHNICAL PRESS TO THE GOOD ROADS MOVEMENT.*

By Hyndman Irwin, B.A.Sc.,

ENGINEERING literature has as important a mission to fulfil in the field of highway work as it has in any other line of municipal or national development. It would not be difficult to substantiate a claim that it bears a much heavier responsibility here than in other phases of engineering work. For, in the road movement, as we of the present generation are obliged to regard it, we have many transitory practices to supplant, many precedents to uphold and many innovations to establish. The principles of dynamics, unchanged, of course, are served up in new and dissimilar ways, because of the variableness of traffic, climate and quality of materials. Generally speaking, each piece of work differs in several essentials from every other. The problem of making a dollar do the most work has innumerable counter-claims and conditions attached to it.

The successful engineer of to-day is necessarily a most diligent consumer of engineering literature. It is the most valuable instrument at his command. By it he acquires a knowledge of the experience and findings of others. To the highway engineer this knowledge is quite indispensable, particularly at this time when we are in the throes of revolutionary tendencies occasioned by the co-mingling on our thoroughfares of diversified methods of travel, heavier loads, increased speeds in every season, over arteries of commerce and pleasure fed by longer and more numerous tributaries than ever before. It is the lot of the road expert to strive constantly against the repellency of nature and the added negative influences of the transportation of man and his effects. The question of expenditure seldom allows him a conquest that is forceful and positive, but he is obliged to be satisfied with a compromise which is temporary and in need of constant vigilance. He cannot expect his own personal judgment and experience to carry him over all the difficulties of his work. In fact, without a knowledge of the experience of others he is unable to judge from an economic standpoint the success or failure of his own. Modern highway improvement and maintenance do not entirely submit to old and well-defined principles that, once inculcated, serve for all time. New methods, new machinery, new materials, up-to-date organization and management—these are vital points in the foundation upon which the good roads movement of to-day depends. Without a working knowledge of them the road man is not suitably equipped for his work. This knowledge, however, can be acquired in a sufficiently comprehensive degree in only one way—through the pages of the technical press.

In dealing with the relation of the technical press to the good roads movement one must include under the general title not only periodic literature, such as technical and trade journals, bulletins, proceedings of engineering and road organizations and reports of governmental departments, but also books, pamphlets and catalogues. They are all of value to the road expert. From catalogues, for instance, he obtains information respecting new machinery and appliances, their general construction, capacities, efficiencies and costs. This information is a very important asset, as the problems of road construction, maintenance and repair, from the viewpoint of the road superintendent, are largely a matter of machinery, and are rapidly providing steady employment for men who have had a training in mechanical work. Likewise the publications of producers of road materials contain information scientifically compiled and arranged in a manner that admits of ready assimilation without material effort or study. Government books of records and statistics of physical and climatic conditions, reports of official tests, etc., are of great value. In short, there are many elements of the technical press which should be included. It is the purpose here, however, to refer to the class of technical literature for which the road man is obliged to pay money, viz., books and periodicals, and define their degrees of usefulness in the general establishment and upkeep of road systems.

With the publishing houses pouring forth an avalanche of new books, it is, perhaps, opportune to observe that there are many classes of books, as well as many books on road engineering and administration. This applies, of course, to literature of all descriptions, but as at this juncture of the road movement so much dependence is to be placed on written thought, attention may well be called to its varying qualities.

Books may be based upon right or wrong theories; they may describe good or poor practice; they may be well or poorly written. Their contents may consist of old material in new garb, or valuable and unpublished facts in unreadable form. Books may be evenly balanced, smoothly written, comprehensive treatises of principles, or they may be misleading and unreliable accumulations of jumbled notions. How often we find in our libraries two books on the same subject, one a veritable interest-binder, and another as difficult to read as a blue book on banking statistics. Again, a book may be abnormally padded with the apparent view of approaching the size of a higher-priced volume, while its antithesis is found to possess, in concise and logical manner, thoughts that are exceptionally clear and every thought in its proper sequence with its antecedent.

Comparatively few road men have large sums to invest on the literature pertaining to their work, but when a man on the job wants information of a technical character he generally wants it badly, and he is not generally so located that he can examine the reference books in the library or the samples on a publisher's shelves in order to ascertain whether or not the information he desires is contained in the books which would there be presented to him for examination. Not every man knows, moreover, just what the information which he desires to secure will entail in the matter of such examination. Book-purchasing under these circumstances bears a marked resemblance to the old-time horse trade, in so far as hidden qualities are concerned. The book purchaser, however, is not distrustful of the author or publisher, and is more likely to infer that the book is a good one, else it would not have been published. The circulars descriptive of the scope and qualities of the published work should naturally be expected to bring out the good points which it may possess, but other features, perhaps undesirable, may be quite overlooked. It is to be remembered that among the very reputable publishers of engineering works, even the best are not immune from misjudging a manuscript which may, when published, prove to fall very short of expectations, and to be unauthentic in some of its important statements.

Evidently the selection of sources of technical information is an important one to the road expert. Briefly, the reviews of newly published books, to be found in the

* Extracts from paper read at the First Canadian and International Good Roads Congress, Montreal, May 20th, 1914.

recognized technical journals, have gradually become, through a process of evolution, beginning with a general rehash of the author's preface, an unprejudiced and straightforward summary of the scope and fundamental features which a book may possess. Journals that devote space to them are cultivating the practice of careful criticism. The result is noticed in the discrimination on the part of the publisher in the matter of sending books to these journals for review. The publisher who desires to increase the sale of an unlikely book would rather have it left unreviewed than severely criticized; hence, the reader may safely increase his dependence upon the books which are reviewed in such journals, provided the review discloses an indication of the sort of information he is after.

The value of keeping up-to-date in technical reading cannot readily be overestimated. This is so widely recognized that little reference need be made to it here. There are books on roadwork that are out of date in many of their statements before they have been in print for five years, or even less. Th growth of road literature as a result of new types and new methods is a fair example of the varying tendencies of general practice. In order to keep pace, therefore, with the new developments in the field of road-building it is necessary to be in touch with the best technical literature of the day on the subject.

Reverting to technical periodicals on roads a century ago, they were practically non-existent. Since then the inception of numerous local and national organizations, with their proceedings devoted to papers and discussions presented in their meetings, and the birth of scores or more of technical journals, also of thousands of trade publications issued by manufacturers, have more or less adequately responded to the need for the broadcasting of information.

Evidently there is the necessity for careful selection on the part of those having to do with this movement and its literature. No man can read by any means all of the information which is presented. Yet the old saying that "experience is the best teacher" was never truer in any line of industry, it being universally accepted, of course, that no man can ever expect to achieve success if he depends solely on his own experience for enlightenment. It is upon the experiences of others, as already stated, that he very largely depends, and in the record of such experiences lies the reason for the existence of the technical press. The technical journal benefits its readers by conveying to them first-hand the sort of information that is not yet to be found in the pages of treatises on the subject. It outlines methods of doing work that are newer and better than others. It describes the maiden efforts of machinery, tools, and processes recently devised. It thoroughly investigates the achievements of progress, and endeavors to present them in the most acceptable way for the general good of mankind. It is, therefore, an indomitable factor in the equipment of the man associated with the good roads movement.

The problem of culling from the growing mass of road literature that which he needs most is an important one for the road engineer. To illustrate its extent we may refer to the recently issued Good Roads Year Book for 1914 of the American Highways Association. It is found to contain a section devoted entirely to a summary of articles published in 1913 in the various journals devoted to the movement. It lists over 650 articles published in that year alone, besides innumerable bulletins, circulars, pamphlets and documents. Evidently there is plenty of material with which a man may equip himself, but a wise selection is a difficult matter.

Of course, the roadman is not alone on the problem. The publishers of this information are fully aware of it, recognize its importance, and are endeavoring to present the desired information in such a way that he can readily make practical use of it. The rest devolves upon himself, and in this age of specialization the problem is not without serious difficulties. The roadman is unwise if he limits the scope of his reading to that which satisfies his immediate needs, and them alone. A man interested therein is also interested in methods of surveying, drainage, construction of dams and bridges, mechanical operation of machinery, transportation of materials, use of cement and concrete, geology of rocks and clays, and the road laws of the country. Manifestly, there is no defining line between his work and that of men in numerous other phases of development. Therefore, if a road engineer is judicious and discreet he will read that literature which pertains to his own special work—and much more.

Finally, there is the important question of the preservation and filing of technical literature. This applies chiefly to periodicals. Once in a while the road man may be unable to peruse his journals as he would like owing to press of duties. He may glance over an article that promises to be of value to him, but is obliged to lay it aside for further consideration, and it may be misplaced or forgotten. The obvious solution lies in the method adopted by almost every up-to-date engineer in other lines of work—that of carefully examining the journal when it is received, and having all articles that have a bearing upon his work listed in a card index system. In a few years every phase of work with which he has to do will be well represented. If he has been wise he will have had his periodicals bound. He is then equipped with a library of information that is of the greatest value to him. He may, for instance, meet a problem which requires additional knowledge of sub-drainage. His card index immediately brings before him a summary of all the information on the subject that has been published by his journals since he began the system, and reference to the articles indicated places him in possession of the required data. They are not the opinions of one man, but of many. Moreover, they are not from an early edition of a volume that has since been succeeded by others which may not be in his possession. He has all the information of intervening years before him. His is not necessarily a voluminous and costly library, but one that is ready to serve him well in more ways than one. Besides acquainting him, on the publication of each issue, of the new methods and new machinery just sprung into use, and of road activities in other countries and in other sections of his own, his periodicals if used in a scientific manner, soon create a reference library for him of excellent quality that can be added to at small cost as years go on, the whole system thereby becoming more valuable.

A principle which is applied by furnace foremen for judging the grade of matte and sometimes also in judging the furnace, is by the fracture of the small sample usually taken at the time of tapping. At the Old Dominion smelting works at Globe, Ariz., the components of the furnace charge are exceedingly variable and often result in abrupt changes in the running of the blast furnaces. Slag samples are taken by a small shallow ladle and are approximately the size and shape of the usual matte sample at most smelting works. The slag "buttons" from each furnace are arranged by the sampler in regular order in a small tray and the foreman judges by the microscopic characteristics of the fracture whether a furnace demands attention. It has been found that the old employees become excellent judges of the fractured slag sample and the system is a great convenience on the night shift.

MINE TUNNELING.

DURING the past few years great progress has been made toward safer, more efficient, and more economical tunneling methods. This advance is partly due, no doubt, to the recent increase in the number of tunnels and adits driven for developing and draining mines and transporting ore. The United States Bureau of Mines, during 1911 and 1912, made a special examination of this phase of mining operations, in connection with an investigation of mining methods and means for preventing accidents. The details especially studied were the provisions for the safety of employees, the kinds of equipment, the methods of driving, and the cost of construction. The results and conclusions obtained from that investigation are discussed and summarized in Bulletin 57, of the Bureau. It is entitled "Safety and Efficiency in Mine Tunneling."

This bulletin is confined chiefly to a discussion of tunnels and adits for mining purposes, such as drainage, transportation, or development, but it also discusses those used to carry water for power, irrigation, or domestic use, in which essential features are practically identical with mine tunnels.

Most tunnels of the sort discussed are driven through rocks at least fairly hard in contrast to ordinary soil, quicksand, and other heavy material of a treacherous nature, and practically none is driven through recent river-bed deposits. Therefore, descriptions of the special methods and equipment for tunnel work in such materials are omitted. A distinction is made between tunnels or adits for which the excavation is wholly or in a large part in material containing no ore and those that follow a vein. As far as possible, the discussion is limited to the former, because the methods employed in driving along a vein are usually more akin to the distinctive operations for removing ore and are, therefore, not so apt to be good examples of tunnel practice.

It has been suggested by prominent authorities that the word "tunnel" be restricted to the designation of such nearly horizontal passageways as extend completely through a mountain or hill from daylight to daylight, and the words "adit" and "drift" be used only for nearly horizontal galleries that enter from the surface and serve to drain a mine or furnish an exit from the workings but do not continue entirely through the hill. Such definition is eminently desirable from strict technical consideration, and would contribute to precision of usage, but, although the suggestion was made over thirty years ago and has been repeated several times since, such usage is not widely established. The American practice of referring to any horizontal gallery as a tunnel, without regard to whether it extends completely through a hill, is so firmly fixed in mining literature and among mining men in this country, even being embodied in the United States mining laws, that the use of a more precise definition has been thought scarcely justifiable in this report.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.

A meeting of the Institute will be held at 55 West 44th Street, New York City, Thursday evening, June 11th, 1914, at 8 p.m. The special order of business will be the question of "A Memorial to Alfred Noble"; also Consideration of Changes in the Constitution and By-laws, recommended by the Special Committee appointed at the last annual meeting.

Coast to Coast

Montreal, Que.—Towards the end of the last week in False Creek have been practically completed.

Liscombe, N.S.—The cost of construction of the lightship, Halifax No. 19, which was recently wrecked off Liscombe, N.S., was $175,000. The contractors were Bow, McLaughlin & Co., of Glasgow, who were under contract to deliver the vessel complete at Halifax.

Montreal, Que.—The thirteenth annual report of the Montreal Light, Heat and Power Company shows substantial gains in gross revenue and net earnings. The gross revenue was $6,245,697, an increase of $736,141, and net earnings amounted to $3,467,246, an addition of $286,130.

Victoria, B.C.—It has been stated by Mr. D'Arcy Tate, vice-president of the P.G.E. Railway Company, that contracts have been awarded for the grading of that line from Fort George to Lake La Hatch, which means that construction will now be carried on from the coast to Fort George.

Ottawa, Ont.—The Dominion House of Commons passed estimates on May 24 for the department of public works amounting in all to approximately $25,000,000. Appropriations for public buildings amounted to $15,250,000. Of the sum, $4,500,000 was for buildings in Ontario. All the estimates for river and harbor improvements with the exception of those in Ontario and Quebec were passed.

Montreal, Que.—Towards the end of the last week in May, it was expected that the "break up" or excavation of the upper part of the C.N.R. tunnel at Montreal would be completed in that part of the work actually under the mountain; and a new stage in the construction reached. Excavation work will still have to be completed, however, in the portion of the tunnel underlying the city streets and for about 700 feet at the west portal. The site for Mount Royal Heights station is also being excavated.

Trent Canal, Ont.—The estimated cost of the new work on the Trent Canal for which tenders are now being called, e.g., Section 3, is placed at $1,500,000. The section to be enlarged lies between Peterboro' and Lake Simcoe. It has been announced by the minister of railways and canals in the Ottawa House that the entire canal will be finally completed at the increased depth within 4 years. The present contracts are all under way; the lower sections between Hastings and the Bay of Quinte will be opened for traffic this autumn.

Fredericton, N.B.—It is stated that the I.C.R. freight sheds at Fredericton are among the best along the entire system, both in size and equipment. The building is a wooden structure, 304 feet in length and 30 feet wide, and can accommodate 10 cars at once. Seven switches run into the sheds with a possibility of more being constructed. The equipment at the new freight sheds is entirely new. There are two excellent loading and unloading platforms and one machinery platform, the last being used to load and unload heavy machinery.

The Pas, Man.—Work commenced on May 25 on the grade upon which steel is to be laid to the terminal grounds of the Hudson Bay Railway. Beginning at a point south of the big bridge across the Saskatchewan river, at The Pas, two tracks will be laid, one to the round-house to be located at the foot of Eighth street, and another to connect with the C.N.R. about a mile south of the present station of that road. By June 1, steel is to be at the site of the proposed round-house and active work is to be continued until winter. The plans call for 14 tracks with a capacity of 1,600 cars. Eight of these tracks will be laid at once. As necessity requires the others will be installed.

Montreal, Que.—The result of a test made at Montreal of the emergency water supply from the Lachine canal has been to show that the emergency plant has proven a complete success. It will now be possible at any time to turn the water out of the regular supply conduit, examine the cement work and make any necessary repairs without affecting the city's supply of water. During the time the water was pumped from the Lachine Canal, tests were made every half-hour and the results were found to be quite satisfactory. While not as pure as the regular river supply, it was found that the difference was not of great consequence. The official tests of the canal water used showed an average of 2,000 bacteria per cubic centimetre. The regular city supply is 800 per cubic centimetre.

Montreal, Que.—Among other offers which have been received at Montreal for the underground electric light service along several streets of the city, is one from the Montreal Public Service Corporation which is being placed before the civic board of control. For a term of 6 years, the company supplying everything, the price per lamp would be $137 as compared with $156 by the Light, Heat and Power Company of Montreal. For a contract of 16 years, the Service Corporation offers the lighting at $88 per lamp under the conditions mentioned as compared with $96.40 by the Light, Heat and Power Company. Again, if the city supplied the lamp standards, cables, etc., for a contract of 16 years the price per lamp would be $65, which is about $5 lower than a similar offer by the Light, Heat and Power Company.

Fort William, Ont.—Improvements nearing completion at the city dock of Fort William are making a change in the appearance of that place. A rip-rap retaining wall has been built around the railway embankment, and a roadway has been constructed from the subway to the freight sheds, with a foundation of large rock and a surface of crushed trap. The road is to be improved further when the railway company allows of the widening of it by 7 feet by building a concrete retaining wall for the railway tracks. The sidewalk below the tracks has been widened and the subway is to be roofed with corrugated iron sheeting. Anticipating that the railway company will make further permanent improvements here, this will be the extent of the city work for the present, leaving the balance to be done when the city and railway company have agreed upon what shape the permanent work will take.

Regina, Sask.—It is said that 139 miles of wire will be required for this year's program of electric light construction at Regina. While a good deal of this wire will be required for the construction of feeders from the new power house, at the same time provision is being made for a good many miles of new service in all directions from the city. New poles, which have been purchased, will, when set up, carry 24 miles of single strand wire. Without taking into consideration the cost of labor, an expenditure of $81,456.47 has already been authorized for this year's extensions to the distributing system; and of this sum $53,381 will be spent on wire alone, the balance providing for all the other materials required in the construction of an electric light distributing system. The program for this year's extension provides for 1,000 new services for light and power, as well as for 200 new street lights.

Varennes, Que.—It has been stated that the big brick plant at Varennes, Que., near Montreal, of the Mount Royal Brick Company, Limited, which will be the most modern brick manufacturing plant in the world, and the largest under one roof in Canada, will be in operation before the first of June. The plant will have an output of 120,000,000 bricks per annum. It is claimed, moreover, that the clay belt which the Mount Royal Company possesses at Varennes has been tested in almost all the laboratories in America, and that these tests have proved that the quality of brick made from this clay has greater strength than that of almost any other building brick in the market. Again, the brick machinery, with which the plant is equipped, is so perfect, that from the time the steam shovels take the clay out of the ground, until the brick is delivered on cars, or in barges, in the city of Montreal, they are only handled once, the entire process of manufacture being performed by automatic machinery.

Ottawa, Ont.—Supplementary estimates totalling $17,438,912, which have been tabled in the Dominion House, have augmented the main estimates of expenditure to $208,174,088. Items included in the supplementary estimates are $1,000,000 towards the construction of a government railway to connect Montreal with the Transcontinental, $1,887,100 for new rolling stock and further improvements to the I.C.R., $1,000,000 as a further vote to the Transcontinental railway, $1,000,000 for the Quebec bridge, $1,000,000 for the Welland ship canal, $50,000 for improvements to the banks of the Rideau canal at Ottawa, a revote of $10,000 for Ottawa fuel-testing, roasting building, addition to shed, etc., $500,000 for the harbors of Port Arthur and Fort William, $500,000 for Quebec harbor, $200,000 for the new postal station "A" on St. James street, Montreal, $250,000 for Hamilton harbor works, $100,000 for the Goderich harbor, $40,000 for Port Credit, $58,000 for Nigger Island channel, and $655,000 to complete St. Lawrence dredging plants.

Winnipeg, Man.—A recent report, submitted by J. G. Glassco, manager of the Winnipeg light and power department, to the civic board of control for the fiscal year ending April 30, shows a surplus for the department amounting to $80,000. There was an increase of 50 per cent. in the gross billings for the year, the total for 1912-13 being $638,081.73 as compared with $953,882.88 for 1913-14. The net realizable earnings advanced from $544,736.03 to $842,368.42, or 55 per cent., while the net cash receipts increased from $520,760.67 to $809,966.74, or 55.8 per cent. For the fiscal year ending April 30 last year there was a deficit of $83,432.90. However, the department was allowed for the first 2 years of operation, to charge the deficit up to capital account, but it had to show an actual profit in the third year if a three cent rate for current was to be maintained. The surplus of $80,000 for the second full fiscal year will ensure the maintenance of the three cent rate. In 1912-13 the number of kilowatt hours generated was 39,071,750, as compared with 60,271,385 for 1913-14, an increase of 54 per cent.

Hamilton, Ont.—Hamilton has been considering the purchase of a stone quarry, and members of the board of control have made an inspection of the Dunlop farm with a view to the purchase of this as a civic quarry site. Also the Canadian Quarries, Limited, has offered to sell its plant and property for $65,000, or to enter into a term contract for the city's entire requirements at 85 cents per ton, f.o.b., Hamilton. The latest development in the project is an offer from the Canadian Crushed Stone corporation, proposing an agreement which would give the city an interest of $150,000 in the company's quarries and ensure a constant supply of stone at a reasonable price. The city would be required to enter into a 15-year contract for its entire requirements at $1.00 per ton, f.o.b., Hamilton; while, by entering into an arrangement along these lines, it would mean that if the company, for any unforeseen reason, was compelled to go into liquidation during this 15-year period, the city through the bond ownership or guarantee would become the absolute owners of the quarry plant for $150,000.

Vancouver, B.C.—More than 10 bridges are being constructed over the Thompson river along the line of the C.N.P. railway; and rapid progress is reported. Nearly half of the upper part of bridge No. 1, the structure at Cisco, has been erected and the big span over the river is being built.

The Cisco bridge is about 6 miles below Lytton, and is the first crossing from the Port Mann end of the line. It passes over the C.P.R. tracks at this point. More than half of bridge No. 2, about half a mile west of Lytton, has been constructed and work is now proceeding on the west shore span. Bridge No. 3, a short distance east of Lytton, has been practically finished, with the exception of a big girder which is to be laid when the track is extended. Bridge No. 4 at Basque, No. 5 at the Black Canyon, and Nos. 6 and 7 near Ashcroft, have all been erected. The foundations of two bridges close to Kamloops have been laid; and work on the superstructures will be proceeded with when track is extended. Bridge No. 10, three miles above Kamloops, has been finished. On the section north of Kamloops work has also been well advanced. The foundations for the big trestle bridge over Lyon Creek at Mile 123 have been laid; and preparations are now being made for the erection of the superstructure. Track-laying will be proceeded with when the Cisco bridge is ready for traffic; and then the various gaps on the sections north of the present rail-head will be linked up right through to Kamloops.

PERSONAL.

D. C. A. GALARNEAU has been appointed forester to the Algoma Central and Hudson Bay Railway, with duties which will include supervision of the railway's fire protection system.

W. R. WORTHINGTON, engineer in charge of the sewer department of the city of Toronto, has been appointed to act as examiner in this district for the Royal Sanitary Institute of Great Britain.

C. R. YUILL, successor to Nather, Yuill & Company, of Vancouver, is consulting engineer for the city of Armstrong, B.C., and has just completed plans for the construction of four reinforced concrete bridges for the city.

G. R. BLAIR, who for some time past has been assistant to T. R. Fulton, Ontario manager for the Eugene Phillips Electrical works, Limited, is acting as manager for Ontario pending the appointment of a successor to Mr. Fulton, resigned.

C. L. HOWSE, E.E., of Hamilton, has been appointed manager of the hydro-electric and waterworks systems of Peterborough, Ont., and will begin his duties on July 1st. Mr. Howse has had considerable previous experience with the Hamilton Hydro-Electric Department.

H. L. BROWN has, it is announced, been recommended to the appointment of assistant city engineer of Winnipeg to succeed the late R. D. Willson, who, as our readers will remember, was electrocuted while on a trip of inspection over the city's artesian well system last fall. Mr. Brown has been in charge of the wells.

AGENTS WANTED.

A well-known British manufacturer of sewage disposal apparatus is anxious to get in touch with responsible individuals or firms in Canada who would be in a position to act as their agents and be able to influence business on their behalf.

A British firm engaged in the manufacture of dynamos and motors is anxious to appoint Canadian agents for the sale of their apparatus in this country.

Fuller particulars regarding the above inquiries can be had by corresponding, in the first instance, with Mr. J. J. Salmond, Managing Director, *Canadian Engineer*, 62 Church Street, Toronto.

A NEW SLIDE RULE IMPROVEMENT.

A new patented indicator or runner for slide rules, called the "Frameless" has just been perfected by Keuffel & Esser Co. Every figure on the rule is clearly visible at all times,

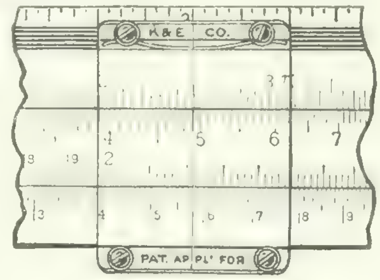

Fig. 1.

there being no side pieces to the metal holder of the glass indicator, and therefore, nothing to hide any of the figures on the rule (see Fig. 1). This is one of the most important improvements in slide rules—those indispensable instruments for rapid calculations.

Many times, after setting the old style indicator or runner, the user would find that he could not read the result because important figures were hidden by the frame or holder of the glass, (see Fig. 2). Frequently two, and sometimes, four or more figures would be thus hidden; causing more or less inconvenience and uncertainty in reading the slide

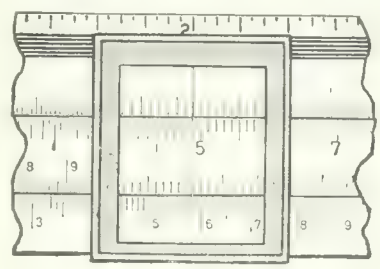

Fig. 2.

rule. The new runner entirely obviates this difficulty, and vastly increases the ease and rapidity of using the rule,

Thousands of engineers and scientists in every profession and industry, as well as contractors, builders, architects and merchants have found the slide rule invaluable as a time and brain saver in quickly and accurately making a great variety of calculations. In its various forms, it has been adapted to the needs of practically every line of work, including all branches of engineering, as well as chemistry.

The 6th International Congress of Mining, Metallurgy, Engineering, and Economic Geology, will be held in London July 12th to 17th, 1915. The Congress will be divided into sections corresponding to the above. The last Congress was held at Düsseldorf in 1910.

Word has been received by the Hon. Louis Coderre, Minister of Mines at Ottawa, to the effect that a British company with a Canadian connection, the Oil Processes, Limited, is going to spend a sum in excess of $2,000,000 in a systematic and exhaustive search for petroleum in Northern Alberta.

The blast furnaces at the Washoe Works, Anaconda, now have water-jacketed tops. Riveted-steel jackets proved unsatisfactory. The best form has been found to be cast-iron jackets, about 2½ in. thick, the iron being cast around a grid of 1¼-in. pipes, connected by U's at the ends, the individual pipes being about 1 in. apart.

ORDERS OF THE RAILWAY COMMISSIONERS
OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21854—May 22—Approving location Edmonton, Dunvegan and B.C. Ry., through Tps. [illegible], Rgs. [illegible], W. 5 M., Alberta.

21855—May 22—Approving location Edmonton, Dunvegan and B.C. Ry., through Tps. 74-77, Rgs. 18-19, W. 5 M., Alberta.

21856—May 22—Extending collecting and delivery limits of Express Companies in town of Outremont, Quebec.

21857—May 23—Dismissing application Tp. Cleveland, Que., for Order apportioning cost of work on crossings of highways by G.T.R. about 3 miles east of Richmond Station, by closing crossings and diverting road to north-east and along G.T.R. right of way.

21858—May 22—Directing G.T.P. Branch Lines Co., divert crossing, as constructed, mileage 13.6, across its tracks; that Co. open up north and south road allowance as well as east and west road allowance across its tracks, mileage 8.5. Work be done 60 days from date of this Order; cost be borne by Ry. Co.

21859—May 23—Dismissing application Federal Electric and Manufacturing Co., of Montreal, Que., for Order extending collection and delivery limits of Express Companies in said city.

21860—May 19—Dismissing complaint Superior Sand and Gravel Co., Limited, of St. Gabriel de Brandon, Que., against rate charged by C.P.R. on sand and gravel from St. Gabriel de Brandon to Montreal.

21861—May 22—Dismissing application J. H. McPherson, Tp. Beverly, Ont., for Order directing C.P.R. to construct, maintain, operate siding from main line to premises of Applicant, Lot 32, Con. 7, Gore of Puslinch, Co. Wellington, Ont.

21862—May 23—Directing C.N.R. to reconstruct fence between Drumheller and Calgary, Alta., within 2 months from date of this Order; work be done to satisfaction of Engineer of Board.

21863—May 23—Authorizing Mun. Council, village Beauport, Que., to construct 2 highways over railway of Quebec Ry. Light, Heat and Power Co. in village of Beauport, Que.

21864—May 23—Authorizing C.P.R. to construct, at grade, additional track (double track) of main line, Farnham Subdivision, across Champlain St., town of St. Johns, mileage 19.9, Co. put back sidewalk as it was before construction of said crossing and reinstate original grade. Rescinding Order No. 21714, dated April 29th, 1914, authorizing temporary crossing.

21865—May 20—Directing that, within 60 days from date of this Order, C.P.R. install improved type of automatic electric bell at crossing of Albert St. at Alliston, Ont., 20 per cent. of cost of installation of bell be paid out of "The Ry. Grade-Crossing Fund," remainder by Ry. Co., all train movements on sidings be flagged over crossing by trainmen of said Railway Company.

21866—May 20—Directing that C.P.R. install gates at St. Maurice, St. Thomas and Bonaventure Sts., city of Three Rivers, Que., 20 per cent. of cost of installation of gates at each crossing to be paid out of "Ry. Grade-Crossing Fund," remainder by Ry. Co., cost of operating gates be paid ¾ by Ry., ¼ by city of Three Rivers.

21867—May [illegible]—Amending Order No. 21691, dated April [illegible] 1914, by adding figures "[illegible]" after figures "[illegible]" in third line [illegible] of Order.

21868—May [illegible]—Dismissing application of William Watters for Order directing G.T.R. to take his property on Ferguson Avenue, City of Hamilton, Ont.

21869—May [illegible]—Rescinding Order No. 14064, dated September [illegible], [illegible], in connection with lumber rates from Routhier, Que., to Montreal, for export.

21870—May 26—Suspending tariff of Duluth, South Shore and Atlantic Railway, C.R.C. No. 331, pending hearing to be held at Ottawa on June 16, 1914, when Duluth, South Shore and Atlantic Ry. Co., and C.P.R. will be required to show cause why said tariff should not be disallowed.

21871—May 23—Authorizing G.T.R. to reconstruct Bridges Nos. 239, Mile Post 209.45, 12th Dist., Tp. Himsworth, Dist. Parry Sound, near Powassan, and No. 247, Mile Post 222.12, 12th Dist. Tp. Ferris, Dist. Nipissing, near Nipissing Jct., Ont.

21872—May 23—Authorizing C.N.R. to construct spur on lane in Block 81 and 120, Regina, Sask., from point on authorized spur in Block 82, old plan 33, and described as subsidiary spur No. 4, with an extension thereof across 6th Ave. and down land in Block 141, and cross Cornwall St. and 5th and 6th Aves., Regina.

21873—May 26—Authorizing Lake Erie and Northern Ry. to construct, at grade, across Air Line Division and Georgian Bay and Lake Erie Division of G.T.R. at Station 1281.58, town of Simcoe, Ont., subject to certain conditions; Applicant Co. to bear and pay whole cost of providing, maintaining, and operating said interlocking plant.

21874—May 23—Approving and authorizing clearances of proposed awning on Toronto Dairy Co.'s premises in city of Woodstock, Ont., subject to company's undertaking to keep employees off tops and sides of cars when operated over spur at Toronto Dairy Company's premises.

21875—May 23—Authorizing C.P.R. to operate trains over bridge No. 144.8 on Portal Sub. Div., Sask. Division.

21876—May 26—Approving detail plans of C.P.R. showing proposed overhead crossing at Eighth Ave. West, Moose Jaw, Sask.

21877—May 26—Directing that Canadian Northern Express Co., publish and file joint tariffs showing express rates on fruit and vegetables from company's shipping point in Prince Edward County to points beyond or via Smith's Falls, reached jointly by said company and Canadian Express Co., or Dominion Express Co., that shall not exceed rates on said commodities published by Can. Express Co. and Dominion Express Co. from Niagara Dist. to same points.

21878—May 28—Directing that C.P.R. provide cabin close to crossing at Cherry St., Toronto, on south side of railway and west side of street, properly heated, and furnished with windows giving clear view up and down railway for more than a block in each direction, for use of flagman to protect public using crossing between hours of 6.30 a.m. and 7 p.m.

21879—May 26—Relieving C.P.R. from providing further protection at crossing of highway second east of Green Valley, Mile Post 47, Co. Glengarry, Tp. Lancaster, Ont., Con. 8, Lot 30¾.

21880—May 26—Authorizing C.P.R. to construct road diversion in Sec. 14, Tp. 11, R. 10, W. 3 M., Sask., and company is authorized to construct, by means of grade crossing, its Swift Current South Easterly Branch Line across said diversion.

21881—May 26—Authorizing Montreal and Southern Counties Ry. to construct across four (4) highways in village and parish of St. Cesaire, Co. Rouville, Que.

21882—May 26—Authorizing G.T.R. to operate its trains jointly with C.P.R. (1) over sidings for E. W. Gillett Co., Limited, south of Liberty Street, Toronto; (2) over tracks of C.P.R. on north side of Liberty St. and lying between point on Liberty St. on which joint tracks of Applicant and C.P.R. end and diamond crossing on Jefferson Ave.

21883—May 26—Authorizing G.T.R. to construct siding into premises of Dominion Foods, Limited, St. Catharines, Ont.

21884—May 26—Authorizing Dist. South Vancouver, B.C., at own expense, to construct Main St. over Vancouver and Lulu Island Ry. in Municipality of South Vancouver, B.C.

A weekly paper for engineers and engineering-contractors

DEAD WEIGHT AND LIVE LOAD

SOME COMPARISONS OF WEIGHTS AND CAPACITIES IN THE FREIGHT AND PASSENGER SERVICE OF RAILROADS IN CANADA, GREAT BRITAIN AND UNITED STATES.

By GEORGE SHERWOOD HODGINS, A.S.M.E.,
Assistant Engineer (Mechanical Department) National Transcontinental Railway.

WHEN one drops a letter into a post-box he seldom reflects that part of what he pays for with the two-cent stamp is really to facilitate handling, and has nothing to do with the subject of his communication. An ordinary business man's envelope for "letter-size" paper is probably about one-twelfth of an ounce and each sheet of paper is possible one-sixteenth of an ounce in weight. It therefore happens that one envelope may contain fourteen sheets of paper, and the whole be below the one ounce which goes for two cents. If this proportion is true, the weight of the envelope is to its contents as 1 is to 14, or, roughly, about seven per cent.

When it comes to the ratio of dead weight or tare to capacity or live load or paying weight, in connection with railway cars, the same style of reasoning applies. The vehicle is the envelope and the paying load is the letter, and the more "letter" you can send and the less "envelope" required the better you are off, because you have less "incidental" expense in the matter. The tare and capacity of cars used here and in the United States differs from those of Great Britain, because the kind of traffic and the method of handling commodities in the countries differ very considerably.

Here and in the United States, the traffic is carried most frequently in box cars, which are permanently roofed and weather-proof. Rough freight or heavy materials are carried in gondolas or on flats. The haulage of shipments of coal, ore or other rough freight often takes place in localities where a huge consignment is carried for long distances without breaking bulk. Freight carried in box or refrigerator cars is best handled where "car-load" lots are insisted on, so that the vehicle may "earn" as much as possible when in service.

In the United Kingdom freight traffic approximates more to what we would call a "magnified express business." A merchant in Manchester, for example, may order a small consignment from a London house, perhaps by wire, and expects his goods to reach him on the following day. Knowing that he can get what he wants on short notice, he probably keeps only a small stock on hand in any case, and the railway company must handle this kind of business without attempting to hold their wagons for "car-load" lots. In fact, the 10-ton capacity goods wagon in England carries, on the average, about three tons.

A year or so ago, a writer in the "American Railway Number" of the London Times, said that "the modern freight car carried 2½ times its own weight and a train of the largest freight cars will transport to the sea-board the product of 5,000 acres of wheat fields." This is, of course, a splendid performance, but the cars carrying 2½ times their own weight have a percentage of tare to contents of 40 per cent. This is much above the post office rate, but it must be remembered that the paper envelope in the mails only makes one trip and is then destroyed, whereas the railway vehicle goes over the road many times and carries a large number of consignments before being relegated to the scrap heap.

Bulletin No. 31, issued by the Bureau of Railway Economics at Washington, D.C., gives the increase of freight car capacity as 28 tons in 1902, up to 36 tons in 1910. This is an increase of a ton a year. The increase has been brought about by the growth in the volume of business in the United States, and the appearance of steady improvement, then apparent, gave rise to the humorous couplet:

"Dear little box-car, don't you cry,
You'll be a freight-house by and by."

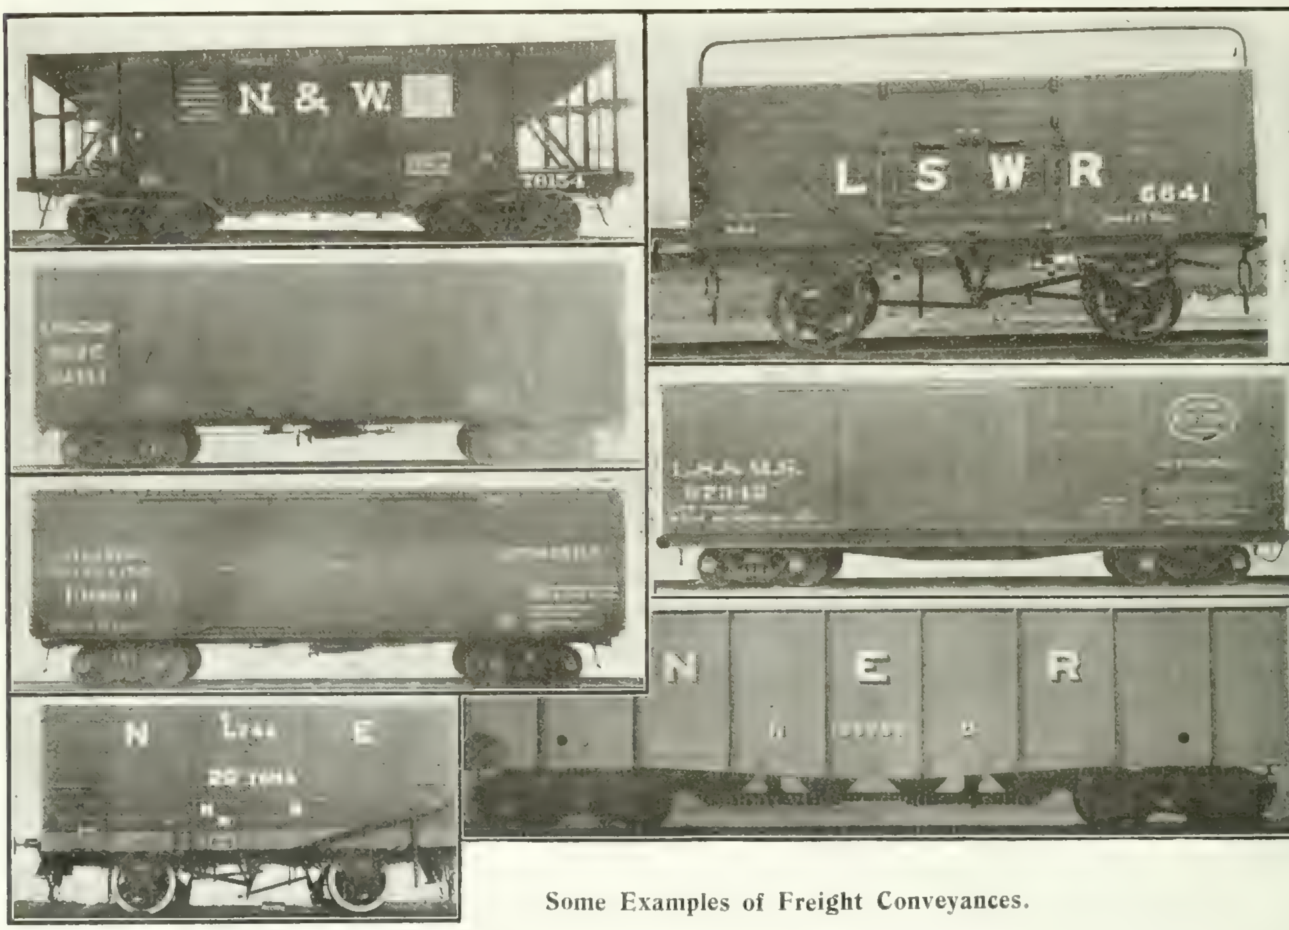
The freight-house on wheels, however, never materialized and much of the prosperity of the Republic was destroyed by laws directed against railroads, enacted by State legislatures which were dominated by a spirit hostile to the "common carrier." There is, however, a reasonable prospect of the return of good times this year.

Our illustrations show, among others, some modern examples. A Norfolk and Western high-side steel hopper gondola, No. 76154, has a capacity of 115,000 lbs., and the tare weight is 41,800 lbs. This gives a ratio of "envelope" to "letter" of 36.3 per cent. The North-Eastern Railway of England, with an open steel wagon, No. 100090, like our gondolas, has a capacity of 40 long tons, or 89,600 lbs., and a tare of 16 long tons, 1 cwt., or 35,840 lbs. This gives a ratio of dead weight to paying load of 40 per cent.

C.P. Box No. 104554, when similarly examined, is seen to have a capacity of 80,000 lbs. and a tare of 38,300 lbs. This gives a ratio of tare to load of 48 per cent. London and South-Western open goods wagon No. 6641, of 15 tons capacity, 33,600 lbs., and tare of 14,784 lbs., gives a ratio of tare to load of 44 per cent. A.C.L. Box 130064, used for the carriage of automobiles, has a tare of 38,000 lbs. and a capacity of 60,000 lbs. The ratio between the two is, therefore, 63 per cent. It must be observed that this is what might almost be called a special car, as an automobile takes up space rather than weight.

A Great Western Railway of England, 10-ton covered goods wagon (shown as nearly as may be, by a L.T. and S.E., somewhat similar vehicle) has a tare of 15,232 lbs. and capacity of 22,400 lbs., and gives a 68 per cent. ratio. Erie Box 107831, with tare 40,200 lbs. and capacity 80,000 lbs., gives a ratio of dead weight to load of 50.25 per cent.

North-Eastern Railway of England open goods wagon No. L. 742, with tare 20,048 lbs. and a capacity of 20 long tons or 44,800 lbs., gives a ratio between the two of 44.75 per cent. L.S. & M.S. Auto-Box 67342, with a tare of 39,000 lbs. and capacity 80,000 lbs., shows a ratio of 48.75 per cent., and London, Tilbury and South End Railway (English) open 10-ton goods wagon No: 1411, with tare 13,272 lbs. and capacity 22,400 lbs., gives a proportion of dead weight to live load of 50.0 per cent.



Some Examples of Freight Conveyances.

(1) N. & W. high-side steel hopper gondola; capacity 115,000 lbs.
(2) C.P.R. box car; capacity 80,000 lbs.
(3) A.C.L. box car (automobile doors); capacity 60,000 lbs.
(4) N.E.R. (English) open goods wagon; capacity 44,800 lbs.
(5) L. & S.W.R. (English) open goods wagon; capacity 33,600 lbs.
(6) L.S. & M.S. box car (automobile doors); capacity 80,000 lbs.
(7) N.E.R. (English) open steel goods wagon; capacity 89,600 lbs.

In these examples we have five Canadian and United States and five British vehicles, and though they are not strictly comparable, because each differs widely in certain particulars from the others, yet a rough and ready comparison may be attempted. The total capacity of the five Canadian and United States cars is 415,000 lbs. and the aggregate tares amount to 197,300 lbs. The ratio of aggregate tare to aggregate capacity gives a percentage of 47.54; and in like manner the five British goods wagons show an aggregate capacity of 212,800 lbs., and the aggregate tare is 99,176 lbs., giving an average of 46.60 per cent.

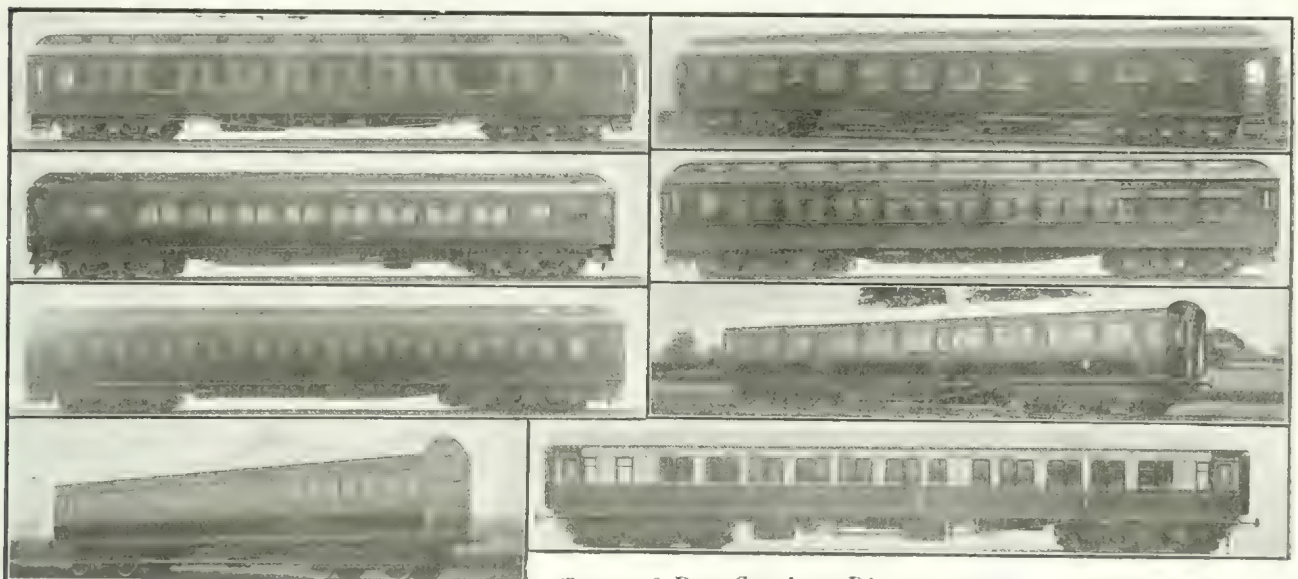
In these two cases there is not much to choose from, but it may be remarked that the Canadian and United States cars contain much greater volume than do those of the United Kingdom, and the former are subject to interchange among the various roads, a practice almost unknown on the other side of the water. This tends to increase hard usage. Weather conditions here are more severe, and everywhere shunting on this continent is far more detrimental to cars than it is abroad. The percentages stand almost even, but with the larger business done here, under severe conditions of service, against the handicap of snow, cold, more numerous grades, sharper curves, and with the strains incidental to long trains and heavy engines, the actual "work" done by the American freight car, carrying more weight per vehicle, cannot be accurately determined by the simple survey of the mathematical ratio representing the proportion of dead weight to live load.

When day coaches and sleepers are taken into account, it is at once obvious that value of the paying "load" cannot be computed by weight, either physical or "moral." It is usually determined by the distance travelled and the accommodation provided. All persons

are considered as practically equal and one dollar as good as another. The relative seating capacity, when compared with dead weight, varies with each coach and in each country. The "value" of each traveller in terms of "pound-miles" is not anything like as uniform a method of rating as the distance passed over or the "dollar-equal-dollar" system would seem to indicate. In other words the dead weight hauled per passenger becomes an important item when the mileage of each coach comes to be made up for a year of continuous service. There are certain things done by railways which cost money and weight and space, which have for their sole object the hope of attracting business, such as the observation platforms on certain coaches or the introduction of library cars on trains. From a purely transportation point of view these things are useless, but as "business-getters," they may be very effective adjuncts.

New York, New Haven & Hartford sleeping car No. 2070 is all wood. The body weighs 99,600 lbs., and the trucks together weigh 44,000 lbs., or a total of 143,600 lbs. There are 16 sections and at night there is accommodation for 32 persons. As a day-coach, which is its maximum load, 64 persons can be carried, and taken this way, a dead weight of 2,243 lbs., for each passenger, is hauled over the road.

The Canadian Pacific Railway sleeper "Granite" is all wood and has two six-wheel trucks, which taken together weigh 40,400 lbs. The body weighs 90,800 lbs., making a total of 131,200 lbs. There are twelve sections, each capable of carrying four persons when the car is used in the day time. Allowing for four persons in the drawing room, the dead weight per passenger is 2,523 lbs. Intercolonial railway sleeper "Sydney" has ten sec-



Types of Day Coaches, Diners and Sleepers of Various Railways.

(1) C.P.R. sleeper "Granite"; weight, 131,200 lbs; carries 52 day passengers.
(2) N.Y., N.H. & H.R.R. sleeper; weight, 143,600 lbs.; carries 64 day passengers.
(3) N.Y.C. day coach; weight, 142,600 lbs.; carries 84 passengers.
(4) N.E.R. (English) bogie, third-class carriage; weight, 64,400 lbs.; carries 80 passengers.
(5) Intercolonial sleeping car "Sydney"; weight, 130,000 lbs.; carries 44 day passengers.
(6) M., St. P. & S. Ste. M. day coach; weight, 126,500 lbs.; carries 76 passengers.
(7) N.E.R. (English) corridor composite dining saloon; weight, 91,840 lbs.; carries 26 passengers.
(8) G.W.R. (English) sleeper; weight, 93,632 lbs.; carries 12 night passengers.

As a typical example of a modern day-coach, first-class, New York Central Lines (Big Four) No. 751 may be considered. This car is an all-steel vehicle, mounted on two six-wheel trucks. The body of the car by itself weighs 98,500 lbs. and the trucks weigh together 44,100 lbs. The total weight on the track is, of course, 140,600 lbs., and seating capacity is provided for 84 persons. There is, therefore, 1,697 lbs. dead weight for each passenger, supposing the car to be full. Another day-coach, No. 991, on the Minneapolis, St. Paul & Sault Ste. Marie, is a coach with steel exterior and wooden finish, seats, etc., inside. The car body weighs 84,000 lbs. The pair of six-wheel trucks together weigh 42,500 lbs. and the vehicle stands on the track weighing 126,500 lbs. and can carry 76 persons. The dead weight per passenger in this case is 1,664 lbs., which is very close to that of the Big Four coach just mentioned. The average, when the weight of the two cars are added together, for the 160 passengers carried by them, is 1,680 lbs.

tions and a drawing room. As a day-coach, i.e., with all available space filled, there is comfortable room foı probably 44 persons, and estimating the total weight of the car at 130,000 lbs., a dead weight of 2,954 lbs. per passenger is hauled.

The sleeping cars here enumerated have together a gross weight of 404,800 lbs., and carry, when each is full up to maximum capacity, an aggregate of 160 persons. The average dead weight per passenger then becomes 2,523 lbs. This is practically equal to the Canadian Pacific sleeper "Granite," which thus represents a typical case.

British passenger rolling stock presents some interesting varieties, though comparison with Canadian and United States coaches is difficult, owing to a variety of circumstances. The Pullman car has been introduced into Great Britain but has never been popular. This is not due to any idea of inferiority of design, equipment or

comfort, but because the English do not care to travel "in bulk," if one may so say, when they are able to pay for the comparative privacy of the compartment. This is no more an example of prejudice than is the preference of the people of the United States, who do not care to be "penned up" in small groups. People on both sides of the Atlantic are gradually modifying their likes and dislikes, as the British are now willing to dine all together in a restaurant car while on the rail, and the traveller on this side is not altogether adverse to the "boudoir" car.

Midland Railway (English) corridor composite (1st and 3rd) No. 2865, weighs 67,720 lbs., and carries 34 passengers. It therefore has a dead weight per passenger of 1,992 lbs. London and South-Western Railway (English) corridor composite (1st and 2nd) coach No. 859, weighs 64,400 lbs., and carries 34 passengers, thus giving a dead weight for each of 1,894 lbs. North-Eastern Railway (English) No. 838, (all 3rd class) weighs 53,312 lbs., and carries 80 passengers. The dead weight for each is 666.4 lbs. These three coaches have an aggregate weight of 185,432 lbs., carry in all 148 passengers, and have an average dead weight per person of 1,252 lbs.

Great Western Railway (English) corridor sleeping car No. 9082 (all 1st class) weighs 93,632 lbs. and accommodates 12 persons. Its dead weight for each goes as high as 7,803 lbs. It is interesting to note from the engraving that this vehicle has the words "sleeping car" on each side. The word "car" is apparently beginning to be used in Great Britain to signify railway rolling stock, as over there the word "motor" is used to indicate what we call an automobile. North-Eastern Railway (English) diner (1st and 3rd) No. 3753, is a corridor composite carriage, weighing 91,840 lbs. and accommodates 26 persons, i.e., 13 of each class. The dead weight per passenger is therefore 3,532 lbs. This N.E. diner No. 3753 and G.W.R. sleeper No. 9082 have an aggregate weight of 185,472 lbs. and together transport 38 passengers, thus the average dead weight per passenger amounts to 4,880 lbs.

The North-Eastern diner is mounted on two six-wheel trucks and, like all other British corridor cars, has what we would call a vestibule at each end. The body is supported on steel frames, and the lower chord is bent down into the form of a bow-string girder. The windows are wide and high and the absence of a running-board along the side is noticeable. Each of the vestibule doors and the two in the side are provided with short steps, almost on the level of the door sill. The Great Western sleeper has no side doors, the two vestibule doors being provided with short steps.

The British form of composite carriage, by which the different classes of passengers are included in the same vehicle, has the advantage of being more in service in certain sections of the country than if each car carried only one class. Where there is steady and regular traffic the single class car is satisfactory, but where traffic fluctuates or where the "classes" presenting themselves at a station do not always appear in approximately the same proportions, the coach carrying more than one class is likely to have a sufficient number on board to constitute a "paying load," if it can be used at all. Whatever security by form or construction, or whatever safety service may be used, all patrons, regardless of "class," are benefited thereby.

Analyzing what figures are before us, it appears that Canadian and United States day coaches show an average of 1,680 lbs. hauled for each passenger carried, while the British day and corridor carriages show 1,252 lbs. per passenger. The Canadian and United States sleepers show 2,780 lbs. and the British sleeper and diner give 4,880 lbs. The British day coaches have less dead weight than ours, and this is to be expected, as British carriages are proverbially light in construction compared to those on this side. The better showing apparently made by American sleepers is probably due to the fact that the sleeper has here been taken with every section holding four persons. As a matter of fact, this does not occur in practice. If each section only held two persons, the average dead weight would be 5,560 lbs. and, taken day in and day out, this probably approximates to actual performance on many trips. A fairer estimate would seem to be the average of the maximum and minimum figures, or 4,170 lbs. average dead weight per passenger.

The British figure is largely modified by the sleeper and diner, here instanced, being very restricted in accommodation for passengers, and it is probable that the British average is much better. These examples not only show the difficulty of making a fair comparison, but demonstrate again, if that were needed, how unreliable is the inductive method where the evidence to be considered is inadequate. The number of examples available is too small and magazine space too crowded for the results of extended investigation, except in the most condensed form. The point, however, stands out clearly that the question of dead weight in railway rolling stock of all kinds plays an important part in economic operating. There are many and important factors to be taken into consideration, and there is before the student an inviting field for research, which perhaps this presentation of the subject may help. The British and American systems are the result of evolution and it is probable that many things which at first sight appear to be glaring contrasts, may shade down to mere differences of practice, or turn out to be like variations which appear in the same species due to local conditions or to the influence of the habitat.

CORROSION OF NICKEL, CHROMIUM AND NICKEL-CHROMIUM STEELS.

Some corrosion tests are described by J. N. Friend, J. L. Bentley and W. C. West in "Engineering," Vol. 93, p. 753, in which disks were prepared of carbon steels, to serve as standards, of nickel steels, of chromium steels, and of nickel-chromium steels, each 0.7 cm. thick and 2.8 cm. in diameter. These disks were kept nearly immersed in tap-water for 64 days, in sea-water for 60 days, in 0.5 per cent. sulphuric acid for 60 days, in 0.5 per cent. sulphuric acid for 53 days, and they were exposed to alternate wet and dry tests for 52 days. The acceleration tests in 0.5 per cent. sulphuric acid gave misleading results, and the two standard steels which showed practically equal corrosion in all the other tests, showed 100 per cent. deviation with 0.5 per cent. sulphuric acid, and with the other steels there were remarkable differences. In some cases there were indications of galvanic action in the chromium and nickel steels in the acid tests, and no chromium nor nickel passed into solution, showing that these elements were the constituents of the cathode. The resistance of chromium steels to corrosion in salt water suggests the use of this metal for ship-building. Nickel steels show marked resistance both to acid and neutral corrosive solutions, the resistance increasing with increased nickel content.

PROPORTIONING OF CONCRETE.

IN correctly made concrete the amount of sand should be just sufficient to fill the voids in the coarse material, and the amount of cement just sufficient to fill the voids in the mixture of sand and coarse material and to coat all the particles with very thin jointing layers. It is a rational assumption that such concrete will give a maximum of strength with the minimum of cost, and if such assumption be justified by experimental results it follows at once that the proportioning of concrete-forming materials is of the utmost importance. Greater strengths can be obtained by the use of excess of cement, as in the case of the ordinary mix of 1:2:4, but the increase in strength is less than the increase of cost of materials and is, therefore, only justified in particular cases.

The strength of any concrete will depend not only upon the materials and their proportions, but also upon the method of using those materials. Any void in a mass of ¾-in. coarse material may be filled in many ways. Firstly, it may be filled with cement and sand mortar, as in the 1:2:4 concrete; secondly, it may be filled with a piece of stone which practically fills the whole space; and thirdly, it may be filled with a number of stones which vary in size with a minimum amount of cement and sand mortar. The first filling is composed almost wholly of joints, and on that account is weak; the second filling is strong, owing to the absence of joints, but it is impracticable; but the third is a compromise which is not only practicable but also strong. It will be seen that the amount of the variations in size or the grading will depend upon the nature and quality of the work required. On the one hand there will be good but costly filling and on the other a cheap but still good filling, and whether the gradiation be large or small the filling will be better than one of cement and sand mortar only.

With a view to testing the effect of "proportioning" upon the strength and other properties, and also the cost of concrete, John A. Davenport and Prof. S. W. Perrott, of the civil engineering department of Liverpool University, drew up a series of experiments, the intention being to test compressive strength, modulus of rupture, specific gravity, water resistance, and fire resistance. Various difficulties arose in the course of the work which prevented the inclusion of specific gravity, water resistance and fire resistance tests. The results were contained in a paper recently presented by them at a meeting of The Concrete Institute, and entitled "Sand and Coarse Material and Proportioning Concrete."

The series involve 216 test pieces, to which must be added others prepared for water and fire resistance and specific gravity tests, but which could not be tested in the time available. The voids were measured in a patent apparatus designed by Mr. Davenport, which gives results to 1/5 of 1%; and which was found to be independent of the observer. The preliminary data comprised tests on Portland cement, size of granite chips, volume of chips per batch, percentage volume of voids in chips, sizes of river-sand used, volume of sand used per batch, percentage volume of voids in sand, and the volume of cement used per batch. Regarding the latter item it must be noted that no allowance was made for the excess cement required for jointing, only the amount required to fill the voids being used. Had time permitted it, the correct allowance in each case would have been ascertained and additional tests made therewith. The limited time made it impossible to test the cement before using it for the concrete testpieces, the brand only suggesting its probable good qualities.

The batches were hand-mixed by engineering students and as no special means of testing the thoroughness of the mix were adopted, the resulting concrete will probably not compare favorably with machine-mixed concrete so far as uniformity of results go. Every care was exercised, however, in mixing to get all the materials thoroughly intermixed and apparently uniform. This proved to be the case when the specimens were tested. The moulds were made of planed boards, bolted together with gangs, damped before using, and lined with paper on the under side to facilitate removal. In spite of this, several pieces were damaged in removal, due more particularly to the relatively small sections used.

Immediately after mixing, the moulds were filled and left in a tool shed till required for testing. They were wetted regularly every three or four days.

It was found that the ratio of compressive to tensile strength varied more in the one-month than in the three-month tests, and is not sufficiently uniform to base any conclusions upon, beyond the fact that such ratio is not constant. It is considered by the authors, however, that this ratio should be more or less constant as the failure, whether compressive or tensile, depends upon the adhesive strength of the cement.

The ratios of strength at three months to strength at one month were more or less uniform, more particularly in the case of comparative strengths. In the case of 1:2:4 concrete the modulus of rupture appears to increase more rapidly than the compressive strength, while in the other series with cement accurately proportioned, the compressive strength increases more rapidly than the modulus of rupture, as out of six series only one runs the other way, probably due to rather dry mixing of those three-month test pieces.

Although the cement tests are unsatisfactory, it will be possible to compare the strengths and costs of the concrete in the different series, as they will probably all be affected to the same extent. The most important point brought out by such comparison is the fact that for accurate proportions, the ratio of cost of cement to total cost is practically constant for all gradings taken in the tests, so that when the graded coarse material is used the total cost need only be further considered. Of course, the total cost is always the final criterion as regards economy, and it may be suggested that the ratio cost of cement to total cost need not be considered. But the relative values of total cost obtained may be altered when additional tests are made at other ages, and it is difficult to say whether they will be affected by the ratio, so that if it can be shown conclusively that this ratio is constant or nearly so, the total cost, age and proportions need only be dealt with.

The authors did not feel justified in attempting to generalize from the results which they obtained, as they considered such results did no more than open up the subject of proportioning and grading in relation to cost. They had no hesitation, however, in saying that the figures given by them show conclusively that the subject is well worth being made the object of special research.

It is announced at Ghent, Belgium, that the third section of the railway line of the Great Lakes will, it is estimated, be completed as far as the shore of Lake Tanganyika, during the second half of the current year as only 50 kilometers of rails remain to be placed and several bridges to be completed.

PROTECTION OF STEEL GIRDERS FROM SMOKE.

The problem of protecting steel work from locomotive smoke has been coped with by the city of Baltimore in an unusual but, up to the present, satisfactory manner. The city engineer, Mr. H. K. McCay, gives a brief description in "Municipal Engineering" of the method followed to protect the steel viaducts directly over railroad tracks throughout the city from the detrimental influence of the gases and cinders from locomotives.

The city of Baltimore is divided by a stream of water which flows from the northwest to the southeast through the most populated districts of this city. The various railroads have utilized the valley of this stream for the purpose of ingress to and egress from the city, laying their tracks along and parallel therewith. Union station, used by the Pennsylvania, Western Maryland and Northern Central railroads, is practically on the banks of this stream. In order to carry the north and south streets in Baltimore across this stream and across the railroad tracks it was necessary to construct at a great deal of expense, five bridges, namely: Guilford avenue, Calvert, St. Paul and Charles streets, and Maryland avenue. Most of these bridges span the railroad tracks at a height which prevents the gas from the engines destroying the steel, but on two bridges, namely, the Calvert and St. Paul street, the clearance is such that the blasts from the engines destroy any protection that is put over the lower members to protect them.

The Calvert street bridge is a magnificent structure, 62 feet in width, with a total length of about 600 feet. The spans are the bow spring type of truss, and made almost entirely of wrought iron. This bridge was built in the year 1878, and cost approximately $220,000. There is a clear span over the railroad tracks of about 146 feet, and a clearance over the Pennsylvania tracks of 23 feet. The author found, as stated above, that the lower members of this bridge became badly corroded from the gases of the locomotives, as many as five hundred of these engines passing under this bridge each day. It had been the practice of the city engineer's department to paint these bridges each year, either with coal tar paint or with the very best red lead paint obtainable. He also found it was nearly impossible to use the ordinary scaffolding to allow time for the paint to harden, therefore he constructed a closed scaffolding, and swung the same beneath the bridge, cleaned off the lower members very carefully and repainted with two coats of paint, allowing the scaffolding to remain as a protection for a week or ten days until the paint thoroughly hardened. In spite of all this protection, it was found that the paint would not stand the blast from the engines, and the lower members, in order to preserve them, had to be painted each year.

Mr. McCay therefore decided to encase the lower members of the bridge in concrete, and careful computation was made as to whether the weight of the concrete would alter the stresses and strains as calculated for this bridge. He found, by removing some ornamental castings, which were of no vital moment to the bridge, that a comparatively thin coat of concrete could be placed on the bridge without increasing the stress or strain, and, if anything, improve the stability of the lower members, thereby reducing to some extent the vibration.

The lower members of the north span consist of nine built-up steel girders, with a surface area of approximately 5,000 square feet. The specifications called for concrete to be put over these members to a thickness of 1½ inches. These girders were carefully cleaned by means of sand blasting and acids, so that all of the old paint was removed, and the steel surface carefully exposed. Wire mesh reinforcement was carried all around the beams, and a coat of "gunite," 1½ inches in thickness, was applied; the gunite following the contour of these beams. The reinforcement is held away from the face of the steel by means of ½-inch iron rods, as it was found that the channel method was not satisfactory.

The total area, as mentioned above, was about 5,000 square feet for the north span of this bridge, and the contract was let at $1.25 per square foot. An additional area has recently been advertised and the contract let at an expense of 95 cents per square foot.

The grout placed by means of the cement gun proved very dense and thick and there is absolutely no danger of gases from the engines penetrating the steel through this grout and Mr. McCay is of the belief that the city of Baltimore has gotten rid of a very expensive renewal item by the adoption of this method.

NITRITE TEST FOR POLLUTION.

In a paper which he read at the recent convention in Philadelphia of the American Water Works Association, Mr. W. M. Booth outlined his use of the nitrite test in tracing a source of pollution in a supply of drinking water, and endeavored to show from experimental results the relation between the nitrites and the existence of the source of probable pollution in a number of cases of springs, wells, streams and lakes. In the instance in question, the author, who has for some time made accasional analyses of a certain water supply at a matter of record, found the nitrites unusually high, accompanied by high ammonias and colonies of bacteria on gelatine. A simple drive well was driven about 8 feet into the ground at numerous points around the wells from which the supply was drawn, and tests for nitrite made on the water pumped from these. By noting which wells showed the highest nitrite, he was able to locate a large amount of decomposing animal matter. The nitrite in the waters from the several wells varied from nothing and .002 to as high as .046 and .044, the latter being found near the putrifying matter referred to.

TIMBERS PRESERVED IN SALT.

In replacing a trestle recently burned along the north shore of Great Salt Lake, according to the "Railway Age-Gazette" engineers found piles perfectly sound after 43 years of service. At another point on the lake, piles 18 in. thick, set 20 years ago, are similarly preserved with salt which has penetrated to their very centre. Timbers in trestles across Salt Lake, placed in 1902, appear to be as good as when they were driven. They have been preserved well above water line by the salt dashed on them by the waves. The first transcontinental telegraph line was abandoned when the railroad was built, and the old poles were sawed off at the ground. An engineer who recently examined the butts in the salt desert near Fish Springs found that, although fifty years had passed since the poles were cut off, the old butts were perfectly sound.

Telephone companies in the Salt Lake valley use salt for preserving poles. When set up, about a bushel of salt is placed around the pole on the ground. The reason why the waters of Salt Lake act as a strong preservative, as distinguished from ocean waters, is because the lake water contains so much more salt, being practically a saturated solution.

MODERN BITUMINOUS SURFACES AND BITUMINOUS PAVEMENTS.*

By Arthur H. Blanchard, M.Can.Soc.C.E.
Professor of Highway Engineering, Columbia University, New York City.

ALTHOUGH bituminous pavements have been in use in American municipalities for nearly fifty years, the introduction of modern bituminous surfaces and bituminous pavements in the construction of highways outside of built-up districts is of comparatively recent origin in America, dating from about 1906. This point is well illustrated by the fact that in 1908 the total yardage of bituminous surfaces and bituminous pavements constructed under the jurisdiction of the eight leading state highway departments in the eastern part of the United States was only 416,700. Since that period the growth of the use of bituminous materials in the construction and maintenance of roads and pavements has been exceedingly rapid.

In order to avoid misunderstandings, the various methods of using bituminous materials referred to in this paper will be explained by the following definitions:—

Bituminous surfaces are those consisting of superficial coats of bituminous materials with or without the addition of stone or slag chips, gravel, sand or materials of a similar character.

Bituminous macadam pavements are those consisting of broken stone and bituminous materials incorporated together by penetration methods.

Bituminous gravel pavements are those consisting of gravel and bituminous materials incorporated together by penetration methods.

Bituminous concrete pavements are those having a wearing surface composed of stone, gravel, sand, etc., or combinations thereof, and bituminous materials incorporated together by mixing methods.

The definitions of bituminous surfaces and bituminous concrete pavements quoted above have been advocated for adoption in the reports of the special committee on "Bituminous Materials for Road Construction and Standards for Their Test and Use" of the American Society of Civil Engineers, whereas the fundamentals of the above definition of bituminous macadam pavements are embodied in the following quotation from the 1913 report of the association for standardizing paving specifications: "If the stone is spread in place and the bituminous cement or binder applied afterwards, the resulting product is bituminous macadam." As sheet asphalt pavements have been in use for many years and as the essentials of good construction have been well established, this type of bituminous pavement will not be dealt with in this paper.

Bituminous Surfaces—Since the formulation of the fundamental principles of the successful construction of tar surfaces by the engineers of the Department of Roads and Bridges of France in 1903, bituminous surfaces have been used extensively in Europe. As an illustration, might be cited the construction of five million square yards of tar surfaces in one county of England, in 1911, under the supervision of the county surveyor of Kent, H. P. Maybury, M.Inst.C.E. During the past eight years American engineers have used bituminous materials in this method of construction and maintenance of roads and pavements.

In the case of broken stone and gravel roads, the most efficient method of procedure is to thoroughly clean the surface by sweeping with hand brooms or horse sweepers and hand brooms, the final sweeping being done with bass or other fine fibre brooms. The bituminous material, which is generally heated, is applied to the surface in amounts varying from one-quarter to one-half gallon per square yard with the aid of pouring cans, hose attached to tanks, hand-drawn gravity distributors, horse-drawn or motor truck gravity or pressure distributors. Some kind of mineral coating is generally applied to cover the bituminous material. The degree of cleanliness of the surface obtained by sweeping will depend to a large extent upon the details of the original construction. It has been found that a road with a thoroughly rolled and well puddled broken stone wearing surface composed of road metal from one inch to two and one-half inches in longest dimension may be easily cleaned and the essential adhesion of the bituminous surface readily secured. This method is characteristic of the modern practice of many of the foremost English and French engineers.

Considerable development has taken place in the use of different kinds of bituminous materials. Tars, both of the water-gas and coal-gas types, continue to be used to a large extent. Without doubt the most comprehensive specifications for the construction of bituminous surfaces with tar are those adopted by the Road Board of England. There has been noted a growing objection to the use of certain asphaltic oils which require from two to three weeks to "set up" to such an extent that tracking will not occur.

Bituminous Macadam and Bituminous Gravel Pavements.—Bituminous macadam and bituminous gravel pavements are of many types, one of the primary differences in construction being the use of one or two applications of the bituminous material. The efficacy of many of the types depends upon the combinations of sizes of broken stone or gravel and the combinations of bituminous materials used when two applications are employed. Variations in types also exist dependent upon the manner in which the different courses may be filled and the treatment of the filled course prior to the application of the bituminous material. The one-application method is very similar in its simplest form to the construction of a bituminous surface except that the bituminous material is applied upon a much more open surface. In the case of the two-application method in certain instances an attempt is made to build up a two-course pavement, while in others the second application is in reality used as a seal coat.

Two of the main difficulties in the construction of bituminous macadam pavements have been to secure a thoroughly compacted wearing course of non-segregated broken stone and the uniform application of the bituminous cement so that the broken stones of the wearing surface would be uniformly bound together. In connection with the above statement should be noted the following excerpt from the 1914 report of the special committee of the American Society of Civil Engineers:—

"An important factor for successful results (in the construction of bituminous pavements by the penetration method) is the thorough compaction by rolling of the road metal before the spreading of the bituminous material."

Two methods which have given satisfactory results will be cited as examples of modern practice.

When the metalling in the wearing course consists of a naturally graded aggregate ranging in sizes from one-half inch to an inch and one-quarter, it has been found unnecessary to further fill the voids by the application of a finer product before the first application of the bitu-

*Presented before the Canadian and International Good Roads Congress at Montreal, on May 20, 1914.

minous material. The character of the product referred to above is shown by the following mechanical analysis:

Percentage passing	½ inch screen	18.9
" "	¾ " "	43.1
" "	1 " "	34.4
" "	1¼ " "	3.6
		100.0

After the wearing course has been thoroughly rolled, from one and one-quarter to one and three-quarters gallons to the square yard of bituminous material is uniformly distributed. Stone chips, free from dust, are then distributed to fill the surface voids. After the chips are rolled a seal coat of one-half to one gallon per square yard of bituminous material is applied. The pavement is finished by the rolling of a second application of stone chips.

As the second method, will be described what the writer considers the most satisfactory type of bituminous macadam pavement at present constructed in England. The bituminous pavement referred to is known by the name of "Pitchmac," and was designed by the city engineer of Liverpool, John A. Brodie, M.Inst.C.E. The following description of the standard method employed in Liverpool is given by Mr. Brodie:

"Pitch grouted macadam has been found to give most satisfactory results in streets of medium and light traffic, and is now being largely used in place of ordinary macadam, and also of more expensive pavements. It is laid to a depth of from 3½ inches to 4½ inches, in two layers. Welsh granite macadam is used, broken to a 2½ inch gauge for the lower layer and to 1½ inch for the top surface. Each layer is put down dry and continually rolled before and after the grouting of pitch and sand mixture has been applied, until the surface is thoroughly consolidated. The foundation is generally of hand-pitched rock, 10 inches deep as for ordinary macadam, but in some cases a bed of 6-inch concrete has been used on main roads. Pitch macadam is also being much used as a surface covering for old boulder pavements, many of which still exist in Liverpool in old streets where the traffic is very small. The cost of pitch macadam may be [illegible] 2¼ cents per square yard per inch of depth."

Bituminous Concrete Pavements.—Bituminous concrete pavements other than sheet asphalt and pavements laid by companies as proprietary articles have received more attention during the past three years than at any time since the days of Abbot, Leverich, Scrimshaw and Van Camp. Less fear of litigation proceedings and the introduction of economical mixing machines equipped with heating attachments have exerted a marked influence. But, furthermore, the rapidly growing recognition of the inherent advantages of bituminous pavements constructed by the mixing method has been largely instrumental in its adoption for traffic conditions for which it is believed to be economical and suitable. Bituminous concrete pavements in which broken stone forms an integral part of the mineral aggregate, may be divided into three classes.

It is self-evident that the simplest type is one having a mineral aggregate composed of one product of a crusher, that is, similar to the product, in the usual type of portable crushing and screening plant, which passes over one screen and through the larger holes of the adjacent screen. This broken stone, in certain cases, may be somewhat uniform in size, but usually such is not the case. In the writer's opinion, an essential element in the construction of this type of bituminous concrete pavement consists in using a product of a crusher which will have a range from an inch to an inch and a quarter in its size. As an illustration will be cited a mechanical analysis of a product which was obtained from a plant where the broken stone passed over a one-half inch screen and through a one and one-quarter inch screen.

Percentage passing	⅛ inch screen	1.2
" "	¼ " "	4.2
" "	½ " "	34.7
" "	¾ " "	40.6
" "	1 " "	17.3
" "	1¼ " "	2.0
		100.0

It is apparent that the above product would not be referred to as composed of uniformly sized stone. It is of interest to note that certain bituminous concrete pavements, having a width of twenty-five feet, constructed with this product of broken stone in 1911 have been subjected to an average daily mixed traffic of two thousand to three thousand vehicles and are at present in excellent condition with no maintenance charges to date.

This type of bituminous concrete pavement has been constructed for many years by using either one or, in certain cases, several courses of broken stone mixed with bituminous cement. As an illustration of the latter method will be cited the practice of one large construction company which builds this type of pavement. The first, or bottom course, of metal coated with bituminous cement ranges from one and one-quarter inches to two and one-half inches; the second course, from one-half inch to one and one-quarter inches; and the third course, from one-quarter inch to one-half inch. The pavement is finished with a dressing of uncoated chips.

Asphalts, tars and tar-asphalt compounds have been used for the bituminous cement. In some cases one kind of bituminous material has been used in the mix and another kind for the seal coat; one of the most common combinations being the use of tar in the mix and asphalt for the seal coat.

As illustrative of some of the details of construction of this type of bituminous concrete pavement which should be covered in contracts, excerpts from specifications recently drafted by Mr. Prevost Hubbard and the writer for the New York Department of Efficiency and Economy will be cited. It should be borne in mind that the temperatures and other limitations specified apply to the bituminous cements and mineral aggregate covered in other sections of the specifications.

"Broken stone for the bituminous concrete shall be heated, as directed, before entering the mixer, to between 66°C. (150°F.) and 149°C. (300°F.) in revolving dryers in which no flame shall be permitted to come in contact with the broken stone and in which the broken stone shall be continuously agitated during the heating.

"The asphalt cement or refined tar shall be heated in kettles so designed as to admit of even heating of the entire mass, with an efficient and positive control of the heat at all times. Asphalt cement shall be heated as directed to a temperature between 135°C. (275°F.) and 177°C. (350°F.). All asphalt cement heated beyond 177°C. (350°F.), either before or during mixing with the broken stone, shall be rejected. Refined tar shall be heated as directed to a temperature between 93°C. (200°F.) and 135°C. (275°F.). All tar heated beyond 135°C. (275°F.), either before or during mixing with the broken stone, shall be rejected.

"When thoroughly heated to the temperature directed, the asphalt cement or refined tar and the broken stone for the bituminous concrete shall be mixed so that the resulting mixture shall contain between five (5) and seven and one-half (7½) per cent. by weight of bitumen as directed. A mixer shall be used, having revolving blades, and so designed and operated as to produce and discharge a thoroughly coated and uniform mixture of nonsegregated broken stone

and asphalt cement. When discharged, mixtures of asphalt cement and broken stone shall have a temperature not more than 149°C. (300°F.), and not less than 93°C. (200°F.), as directed. When discharged, mixtures of refined tar and broken stone shall have a temperature not more than 121°C. (250°F.), and not less than 66°C. (150°F.), as directed.

"The bituminous concrete, heated and prepared as specified, shall be delivered direct from the mixer to the point of deposition on the foundation in trucks or wagons, provided with canvas covers for retaining the heat. As delivered the bituminous concrete shall have a temperature of at least 66°C. (150°F.). Material having a lower temperature than this shall not be laid upon the foundation.

"Rollers used on the bituminous concrete and the seal coat shall be well balanced, self-propelled, tandem rollers, weighing between ten (10) and twelve (12) tons each. Each shall have a compression under the rear roller of between two hundred (200) and three hundred and fifty (350) pounds per linear inch of roll, and shall be provided with an ash pan, which shall prevent ashes dropping onto the bituminous concrete or seal coat.

"As soon as possible after the compaction of the bituminous concrete, when the surface is clean and dry, a seal coat of the hot asphalt cement shall be evenly distributed over the bituminous concrete and spread by means of squeegees as directed. The asphalt cement shall be applied at a temperature not less than 135°C. (275°F.), nor more than 177°C. (350°F.), at a rate of one-half (½) to one (1) gallon per square yard, as directed. A thin, uniform layer of dry, clean, No. 1 broken stone (stone chips) shall be immmdiately spread over the asphalt cement, as directed, by machines or skilled workmen. The spreading of the No. 1 broken stone shall not lag more than twenty (20) feet behind the placing of the asphalt cement coating. Number 1 broken stone shall not be placed on the wearing course before the asphalt cement of the seal coat is applied. The surface of the bituminous concrete shall be kept scrupulously clean until the seat coat is applied, and the contractor shall not permit any hauling over the wearing course before the completion of the seal coat.

"No bituminous concrete shall be mixed or placed between October 1 and May 15, except by written permission, and no bituminous concrete shall be mixed or placed when the air temperature in the shade is below 10°C. (50°F.), or when the foundation is damp or otherwise unsatisfactory."

The second type usually consists of the broken stone composing one product of a crusher and sand or other fine mineral matter mixed together with a bituminous cement. The wearing surface of this mix is sometimes finished by rolling in fine stone chips but generally a seal coat is used together with fine mineral matter for a top dressing. When constructed on a commercial scale, the mineral aggregate is always heated and mixed in a specially constructed machine. Usually the same grade and type of bituminous material is used for the mix and the seal coat.

In the third type of bituminous concrete pavement the composition of the mineral aggregate is definitely covered in properly drawn specifications. As an example may be cited the following method of covering the composition of the mineral aggregate of Warrenite, a proprietary pavement of the Warren Brothers Company, which was used by William H. Connell, chief of the Bureau of Highways, in drafting specifications for the City of Philadelphia.

"Material passing 1¼-inch screen and retained on No. 2 sieve, 40 to 60 per cent. Material passing No. 2 sieve and retained on No. 4 sieve, 10 to 20 per cent. Material passing No. 4 sieve and retained on No. 10 sieve, 10 to 5 per cent. Material passing No. 10 sieve and retained on No. 30 sieve, 10 to 5 per cent. Material passing No. 80 sieve at least 25 per cent.. of which will pass a No. 200 sieve, 10 to 5 per cent. The balance, to pass No. 30 sieve and be retained on No. 80 sieve."

The 1914 specifications of the State of New Jersey contain the following description of the grading of a bituminous concrete pavement similar to the one given above.

Size of Screen.	Percentages, Minimum.	Maximum.
Passing 1½" and retained on 1"	0	15
Passing 1", retained on ½"	40	50
Passing ½" and retained on ¼"	10	25
Passing ¼" and retained on a 10-mesh sieve.	8	15
Passing 10 and retained on a 30-mesh sieve.	12	22
Passing 30 and retained on a 80-mesh sieve.	5	15
Passing 80 and retained on a 200-mesh sieve.	3	8
Passing a 200-mesh sieve	2	8
Bitumen content	6.5	8.5

As another illustration might be cited the well-known Topeka specification, which covers a definite grading of a mixture of broken stone and sand. The Topeka grading is as follows:

Percentage of bitumen ....from 7 to 11
Percentage of mineral aggregate passing 200 mesh screen ....from 5 to 11
Percentage of mineral aggregate passing 40 mesh screen ....from 18 to 30
Percentage of mineral aggregate passing 10 mesh screen ....from 25 to 55
Percentage of mineral aggregate passing 4 mesh screen ....from 8 to 22
Percentage of mineral aggregate passing 2 mesh screen ....less than 10

In the construction of all types of bituminous concrete pavements, in addition to the requirements covering the properties of the bituminous cement and the quality and character of the mineral aggregate, certain essential features should be given careful consideration. The following citations from the 1914 report of the special committee of the American Society of Civil Engineers are specially pertinent:

"Where the character of the traffic justifies the use of a bituminous concrete pavement, the same conditions demand an extraordinarily strong foundation therefor.

"The amount of bituminous material to be used in any case will depend upon the peculiar conditions of that case, such as the kind of road metal and of bituminous material, the character of the aggregate, the climatic conditions, etc.

"The character of the mineral aggregate to be used may be controlled by local conditions, but the best results can only be obtained by the use of the best materials. Excessive sizes or excessive variations in the size of the mineral particles, should be avoided, and the utmost care must be taken to avoid the segregation of the different size particles.

"Mixing machines should be used, and hand-mixing methods should be avoided wherever practicable.

"In the use of a heated aggregate for the construction of a bituminous concrete pavement, non-uniformity or excess in the heating of stone should be avoided.

"Where bituminous pavements are laid, the edges should be protected and a sudden transition from the pavement to any softer shoulder material avoided by means of cement, concrete or other edgings and such reinforcement of the shoulder material as may be necessary."

DIAGRAM OF CONCRETE MATERIALS.

In *The Canadian Engineer* of May 21st, 1914, there appeared a diagram for obtaining quantities of materials required per cubic yard of concrete. This diagram was prepared by R. O. Wynne-Roberts, Consulting Engineer, Regina. A number of extra copies of this diagram have been printed and mounted on stiff board. They should be found of value in estimating quantities and costs. Some may desire to have a copy, mounted as above, on hand for easy reference, thus obviating the necessity of removing a page from the issue in which it was published. Upon receipt of 10 cents to defray postage expense, one of these will be mailed to any address.

DEATH RATE OF WATER BACTERIA.

INFORMATION pertaining to the destruction of bacteria in drinking water and in polluted rivers and streams has come to be regarded as being an important necessity in every community. This, largely for the reason that the knowledge of the danger of pathogenic bacteria to the health of water-users has become widespread.

There enters into the investigation of the degree of pollution and the danger resulting therefrom, the question of the longevity of B. coli. This is necessary in determin-

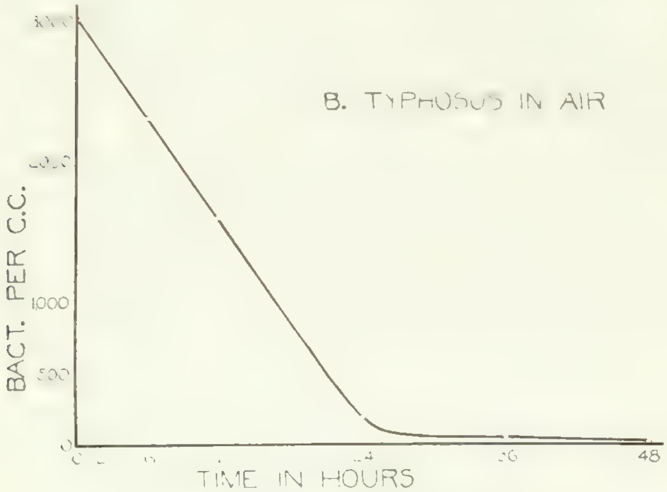


Fig. 1.—Death of B. Typhosus in Air.

ing the length of time a sample of water may be kept prior to analysis. It is also useful in a determination of the volume to be used in such analysis.

In a paper recently prepared by Dr. Otto Rahn, assistant professor of bacteriology, University of Illinois, and Mr. M. E. Hinds, assistant chemist of Illinois State Water Survey, the results are given of experiments made to determine the rate, manner and factors influencing the death of bacteria in drinking water and polluted streams. This paper was presented at a meeting of the Illinois Water Supply Association. From it the following information is secured:

As a number of uncertain factors would be involved in working with a natural water or sewage, it was thought

Table I.—Theoretical Number of Cells Present at End of 60 Hours and for Each 6-Hour Interval.

Hours.	Theoretical number of cells.	Actual number of cells.
0	1,000,000	315,000

60	.0001	

best to work first on pure water under known conditions and to vary the conditions until they finally approached those found in natural waters. The water used for this work was ammonia free, which, however, contained a very small amount of nitrogen. It is purer than ordinary distilled water, being redistilled twice, and is the purest grade of water obtainable unless a large amount of labor is spent on its preparation.

The rate of death of B. typhosus as found by different observers is variable, probably due to different experimental conditions. Of the many contradictory statements concerning the death rate, it is difficult to determine which one is correct as most of the data appear to be reliable. This leaves us in doubt as to whether death is due to lack of food, presence or absence of oxygen, temperature changes or antagonism of other bacteria.

During the last seven years we have learned that bacteria under unfavorable conditions die gradually. Of the total number, a certain percentage will die in a unit of time and of the number surviving the same percentage will die in the next unit of time. As far as we know, this law holds true with all causes of death, whether by disinfectants, light, drying or heat. We know of no exception.

It was only natural to expect this same regularity of death to hold true in the case of B. typhosus and B. coli in pure water. The experiments showed this to be the case. The reduction in the case of B. typhosus was 89.3 per cent. in six hours, that is, after six hours' time only about 10 per cent. of the original number survived. Assuming 1,000,000 cells to be present in the beginning, we find the numbers remaining as shown in Table I., which is based on a reduction of 90 per cent. in each six-hour period.

It is easily seen that we never come to an absolute zero. There are always some bacteria left alive, but the number soon becomes so small, that for practical purposes, we might consider them absent. Table I. shows a reduction in 60 hours from 1,000,000 per c.c. to less than 1 per gallon. Whether such water would be considered safe for use, is questionable. In 96 hours, we would have less than one typhoid bacterium per 1,000,000 gals. Such water would probably be safe. Certainly, no bacteriological or other analysis could discover the bacterium.

B. coli does not die quite as fast as B. typhosus, about 72 hours being necessary to reduce their number from 1,000,000 per c.c. to 1 per gal. Kruse states that B. coli is found a normal inhabitant of all waters, whether good or bad. We can find it, if we only take a large enough sample.

Knowing the facts, we tried to find the cause of death. It is probable that the death of B. coli and B. typhosus in pure water is due to starvation. A sample of tap water was sterilized and inoculated with B. coli and proved to be a fair medium for growth. An initial number of 1,500,000 increased slowly to 3,000,000 in twelve days and then slowly decreased, over half the original number being still present at the end of five weeks, when the experiment was discontinued. At the same time a sample of deep well water with a very high mineral residue was sterilized and inoculated with about 2,000,000 B. coli per c.c. and only 1 per c.c. was found at the end of two days. This death rate was higher than in very pure water. Only a trace of organic nitrogen was present.

It is very important from a practical viewpoint to decide whether or not dissolved oxygen plays any part in the rate of the death of bacteria in water. Whipple and Mayer found B. typhosus died about 20 times as fast without oxygen as with it, and B. coli died about twice as fast. The absence of oxygen was secured by keeping the tubes in an atmosphere of nitrogen and hydrogen. This would suggest a suffocation of bacteria. In our work we have been unable to get the same results with B. coli, as in all of our tests the death rate was lower with-

out oxygen. Our work on B. typhosus bears out the previous work in that the death rate is higher in nitrogen than in air, but the difference is slight as compared with Whipple's, perhaps due to a different strain, perhaps to different water. Figure 2 shows the difference in death rate in air, hydrogen and nitrogen.

The temperature of the water has a direct bearing on the death rate. Even though B. coli and B. typhosus both grow much better at 37° C. than at 20° C., when cultivated under growing conditions, they also die faster at the higher temperature. With B. coli we have found the rate of death to increase 1.8 times with each 10° rise in temperature. Growth and death of bacteria must be looked upon as chemical reactions, and, therefore, must proceed faster at higher temperature within certain limits. In work with B. typhosus in Lake Michigan water, Russell found the death rate increased eight times from freezing to 12° C.

In 1911 Ruediger determined the rate of death of B. coli and B. typhosus in river water under natural conditions both in summer and in winter. He attributes the

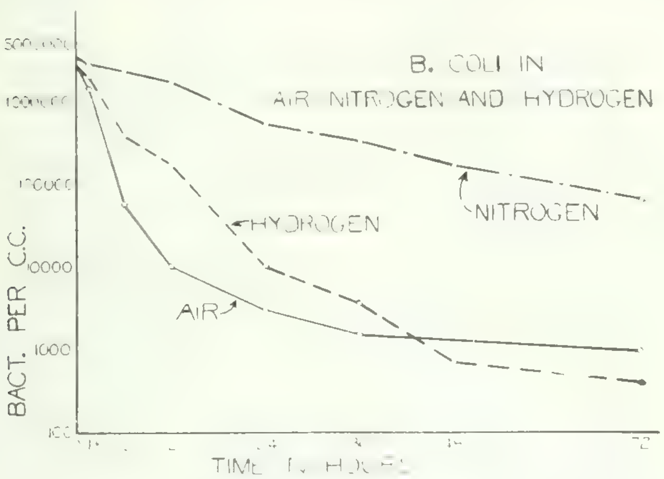

Fig. 2.—Death of B. Coli in Air, Nitrogen and Hydrogen.

faster death rate in summer to the effect of light and to saprophitic plants. We can account for the change in death rate as a change due to the difference in temperature.

Conclusions.—In pure, natural water and in redistilled water, B. coli and B. typhosus die from starvation in the gradual, regular manner observed with other causes of death.

The rate of death increases with the temperature.

The presence of oxygen under these conditions, seems to be harmful for B. coli, but beneficial to B. typhosus.

Further work is to be done on the effect of organic matter, mineral matter, other organisms and the temperature coefficient under these varying conditions.

A NEW STADIA CIRCLE.

THE subsequent computations necessary to reduce observed stadia distances to the correct horizontal and vertical distances have long been a source of trouble and labor to the surveyor. Many arrangements, such as charts, tables, and slide-rules, have been devised to minimize this work, but all have been somewhat complicated and have presented a fruitful source of error. For this reason stadia measurements have not found the universal application which their accuracy and convenience would presuppose.

In the new K. and E. stadia circle an arrangement is presented which will undoubtedly stimulate the use of stadia measurements in all branches of surveying. Not only does this arrangement facilitate the taking of field notes, but it reduces the calculations of these notes to simple arithmetical processes, and, furthermore, the arrangement does not encumber the instrument with complicated and delicate equipment.

The usual method of taking stadia measurements is to observe the interval intercepted on a rod by the stadia hairs and the angle of depression or elevation of the telescope. With this data the observer is then enabled, by using the formulas $H = S \cos.^2 a$, and $V = \frac{S}{2} \sin. 2\,a$, to compute the correct horizontal distance and elevation of the point in question. The mechanical means devised for the solution of these formulas have greatly simplified the plotting of notes, but their use still involves considerable labor and necessitates the carrying of extra equipment into the field.

This new stadia circle is a modification of the regular transit circle, whereby the degree graduations on two opposite segments are replaced by special graduations which give directly the per cent. of the observed stadia distance represented by the horizontal and vertical components.

Through an arc of approximately 60° at the right and left-hand sides of the circle the degree graduations are replaced by the special stadia graduations. At the index marked "Hor." is read the percentage factor to be applied to the observed stadia distance to obtain the correct horizontal distance. At the index marked "Vert." is read the percentage factor to be applied to the observed stadia distance to obtain the difference in elevation between the rod and instrument. Complication in the calculations is avoided by bringing the centre cross hair of the telescope to target or mark on the rod, which has been placed at instrument height before reading H. and V.

Example.—Suppose the observed stadia distance to be 480 feet and the telescope, when sighted on target, to be inclined at such an angle that the reading at the Hor. index is .97 and at the Vert. index .17. Then the correct horizontal distance would be 480 x .97 = 465.6 ft., and the difference in elevation would be 480 x .17 = 81.6 ft.

The simplicity of this arrangement would seem to raise doubts as to its accuracy, but the position of each special graduation is theoretically correct, and exhaustive tests of the instrument throughout the full range of the stadia graduations have proved the device to be practically free from error.

Over a long series of tests by different observers the average error in the reading of the horizontal correction factor was found to be 0.05, which in a 500 ft. sight would introduce an error of 0.25 ft. in the computed horizontal distance. The same trials applied in the reading of the vertical correction factor disclosed an average error of 0.02, which in a 500-ft. sight would introduce an error of 0.10 ft.

By the method of least squares the average error in reading was computed to be: Horizontal + or — 0.09; Vertical + or — 0.07. These larger errors, in a 500 ft. sight would affect the computation of the horizontal and vertical distances by + or — 0.45 and + or — 0.35 ft., respectively, and as the allowable error in stadia work is 1 per cent., it will be readily seen that, in accuracy, this stadia circle compares favorably with any method of computation now used.

USE OF LIQUID CHLORINE AT PHILADELPHIA AND OTHER PLACES.

THE Torresdale intake of the Philadelphia waterworks is in the Delaware River, about 12 miles above the business centre of the city. A review of the results obtained by the filter plant, which has now been in operation at Torresdale for nearly seven years, was given in a paper read by Francis D. West, chemist in charge of the Torresdale Laboratory, and J. S. V. Siddons, superintendent of the filters, before the New England Waterworks Association at its annual convention in September last. The paper contained a general summary of the results obtained with the use of calcium hypoat hand, viz., the results obtained with liquid chlorine, the following information respecting the former process is given:

Bleach was first used at Torresdale in the form of hypochlorite of soda produced electrolytically, during September, 1909. Two cells manufactured by the National Laundry Company were used. A current of 35 amperes at 110 volts was used to decompose a brine solution. The temperature of the bleach solution averaged 110 deg. F. The chlorine and the soda were allowed to recombine, and the temperature was so high that chlorates were formed.

The bleach was applied directly in front of the inlet valve of one of the pre-filters operated at a 20-million-gallon rate, or one-fourth normal. The conclusions were, in part, that the bacterial efficiency of the filter was considerably less than that of filters operated at four times the rate without treatment.

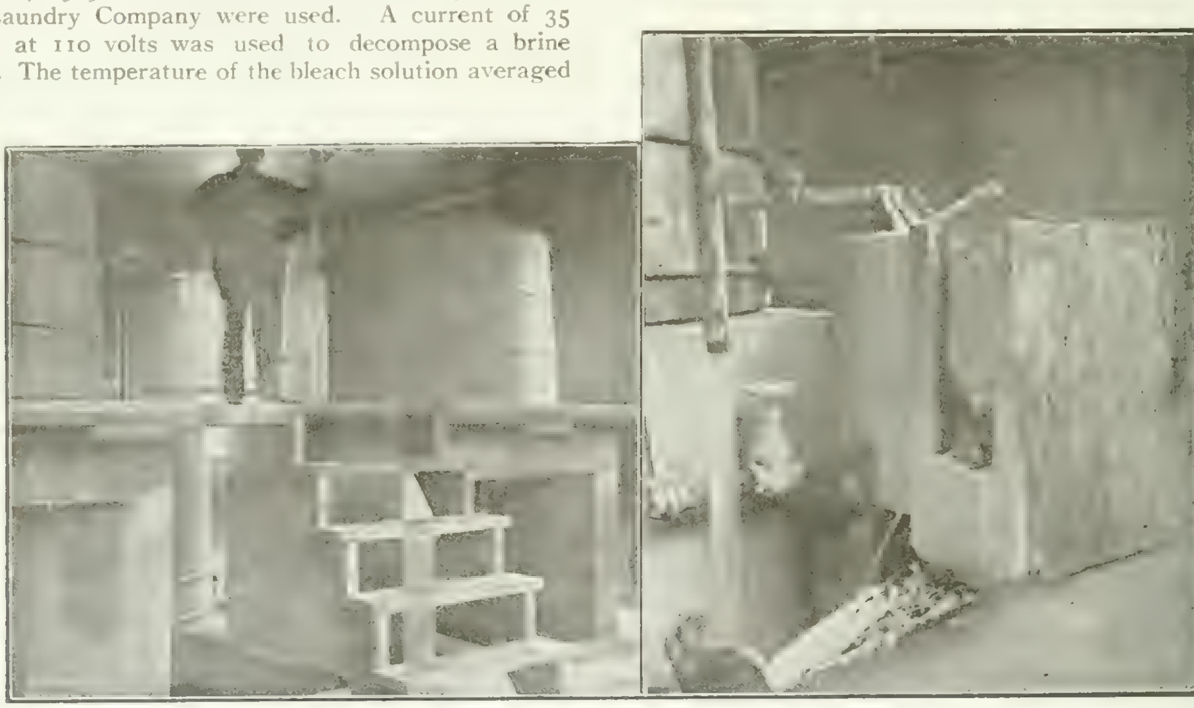
Hypochlorite was again used in December, 1910. Due to the fact that the bacterial efficiency of slow sand filters decreases materially in cold weather, and the fœcal organism, B. coli communis, was present in the filtered water, it was decided to use chloride of lime to disinfect the water in the filtered water basin. Treatment was continued until April, 1911, and stopped until December, when it was again started and used without interruption until February, 1913.

The bleach plant at first consisted of two cedar mixing tanks about 5 ft. in diameter and 4 ft. deep, and one solution tank of the same dimensions, together with a yellow pine orifice tank 2 ft. to a side, which was soon changed to a concrete tank of the same dimensions. After five months' continual service the tanks became so badly perforated that they could no longer be used and were replaced by new tanks lined with 3 in. of concrete.

Fig. 1 shows the mixing and solution tanks and Fig. 2 the orifice tank. Mixing was done by hand, each mix receiving about 2 hours' agitation. From two to six mixes were made a day.

For further details respecting the operation of the plant the reader is referred to the paper mentioned above.

In another paper presented at the recent convention of the American Waterworks Association, Mr. West deals in detail with the use of liquid chlorine. In the course of his paper he presents the following objections to the use of hypochlorite of calcium and the method by which it was applied at the Torresdale filters:



Views of Torresdale Bleach Plant. Fig. 1 (left)—Mixing and Solution Tanks. Fig. 2 (right)—Orifice Tank.

(1) Variation in the strength of solution, due to variable quantities of available chlorine in the powder, and to the variation in the readiness with which the bleach mixes with water.

(2) Interruption to feed of solution, caused by corrosion of orifice or stopping of flow by lumps of sludge or choking of delivery pipe.

(3) Tastes and odors which create in all probability the most serious objection.

Historical Sketch of the Use of Liquid Chlorine in United States.—The credit for the introduction of liquid chlorine for water disinfection belongs to Major C. R. Darnell, who first tried it in June, 1910. He applied the chlorine in the form of a dry gas to the water to be treated. He later carried out a series of tests with an apparatus with a capacity of 500 gal. per hour.

In June, 1912, Dr. Geo. Ornstein constructed an experimental apparatus for the use of chlorine gas for water

and sewage sterilization employing a principle entirely different from Major Darnell, involving the absorption of the gas in water prior to its application to the fluid to be treated.

In September, 1912, S. M. Van Loan, Ass't-Chief Engineer, Philadelphia Bureau of Water, assisted by Geo. E. Thomas, chemist, Belmont Laboratory, experimented with liquid chlorine on a large scale at Belmont filter plant. They fed the chlorine into the filtered water basin in the form of gas, regulating the quantity by loss in weight of the containers; about 46 lbs. per day being applied to 36,000,000 gals. of water. With the approach of cold weather, the difficulty of freezing was encountered. Later the cylinder was jacketed and heated by a lamp.

Early in November, John A. Kienle, then chief engineer of the water department of Wilmington, Del., worked along similar lines at the Wilmington plant. By the use of high- and low-pressure valves he was able to regulate the flow of gas. His results were presented at the 1913 convention of the American Water Works Association. He worked in conjunction with the Electro-Bleaching Gas Company, who installed their apparatus January, 1913. This apparatus makes use of an absorption tower, whereby the chlorine is absorbed by a small amount of flowing water which carries it into the supply to be treated.

About the same time Dr. D. Jackson was experimenting at Ridgewood reservoir, Brooklyn, and shortly afterward put out the Leavitt-Jackson liquid chlorine machine. This machine operates on the basis of a balanced beam, feeding the gas according to loss in weight. The gas is fed directly into the water to be treated similarly to the Darnell apparatus.

The first complete set of results for a continued period are those from the Niagara Falls plant operated by the Western New York Filtration Company, under direction of H. F. Huy.

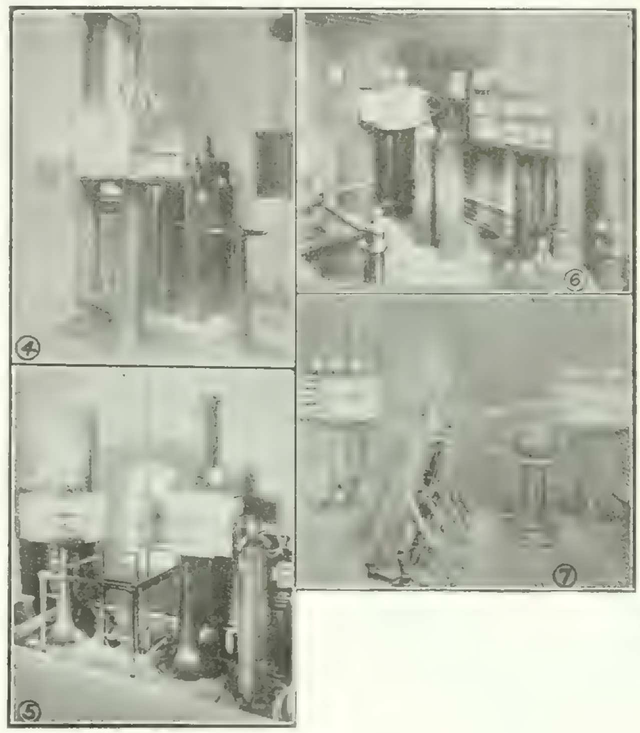
The first permanent liquid chlorine plant in Philadelphia was installed at Queen Lane filter plant September, 1913. A contract for 10 plants, two at each of the five filter plants, was awarded the Electro-Bleaching Gas Company for $9,750. The plants were installed during October and November, 1913; that at Torresdale starting November 25th. Fig. 3 shows the present liquid chlorine installation at Torresdale. Figs. 4, 5, 6 and 7 show similar plants at Queen Lane, Upper and Lower Roxboro and Belmont, respectively.

General Description of Apparatus.—From 4 to 8 cylinders of liquid chlorine are connected by means of flexible copper coils to a manifold with a valve for each cylinder. The manifold is connected with a gauge used to determine initial pressures. Beyond this gauge are two regulating valves; the first reducing the initial pressure to about 15 lbs. per sq. in. and the second regulating the pressure through a range sufficient to give the desired amount of gas. A low-pressure gauge, calibrated empirically, indicates the flow. The gas then passes through a ⅜-in. hard rubber pipe to the bottom of the first absorption tower. This tower is 8 ft. high and is filled with coke to give surface, and is sealed. The excess gas passes through a second pipe to the bottom of a second tower.

These towers, as well as all other parts from this point on, are made of hard rubber. Water is admitted through the top of the towers.

The chlorinated water passes through a horizontal pipe 58 ft. long 4 in. in diam. connected with eight drops ¾ in. in diam. extending to within one foot of the bottom of the chamber and protected from the current by 1½-in. iron casings. About three feet of flexible rubber hose is attached to the ends of these pipes. The ends of the hose are kept in motion by the swirl of the current.

Original Apparatus and Changes Thereto.—Owing to the large quantity of chlorine needed (as high as 10 lbs. per hour) it was planned to feed the chlorine in liquid form through the cylinder valve having an evaporator placed next to the high-pressure valve. This was done to prevent freezing owing to the reduction in temperature due to the rapid evaporation. Cradles were provided for inverting the cylinders. The evaporator was prevented from freezing by having a constant flow of water passing around it.



Views of Liquid Chlorine Installations at the Schuylkill River Plants in Philadelphia. Fig. 4—At Queen Lane; Fig. 5—At Upper Roxborough; Fig. 6—At Lower Roxborough; and Fig. 7—At Belmont.

From almost the start trouble was experienced. The needle and regulating valves of the apparatus gradually choked up with the impurities in the chlorine cylinders chiefly ferric chloride mixed with an oil-like substance with the consistency of petroleum. Liquid chlorine was allowed to pass through the feed pipe of the tower, corroding and choking this up, and found its way through the coil in the evaporator where it came in contact with the water used for cooling and the whole apparatus went out of commission.

When it was found impossible to supply the gas in this manner the cylinders were used vertically and an electrically heated cabinet with automatic thermostatic control was installed. This keeps the cylinders at a temperature of 75 deg. F., and but little trouble with freezing is experienced.

Results at Various Plants.—The paper then outlined the results from treatment at Torresdale, Belmont, Upper and Lower Roxborough, Queen Lane, Niagara Falls, N.Y., Wilmington, N.C., and Wilmington, Del.; comparing, whenever possible, in each case the chlorine with

corresponding hypo data. It also included results of liquid chlorine treatment with unfiltered water at Montreal. The Torresdale comparative results are given in the table at the foot of this page.

Advantages of Liquid Chlorine Over Chloride of Lime.—The author then dealt with the claims made for liquid chlorine, an analysis of which may prove of value.

(1) Liquid chlorine is an absolutely pure chemical, concentrated in small cylinders while chloride of lime is bulky, requiring large space for storing.

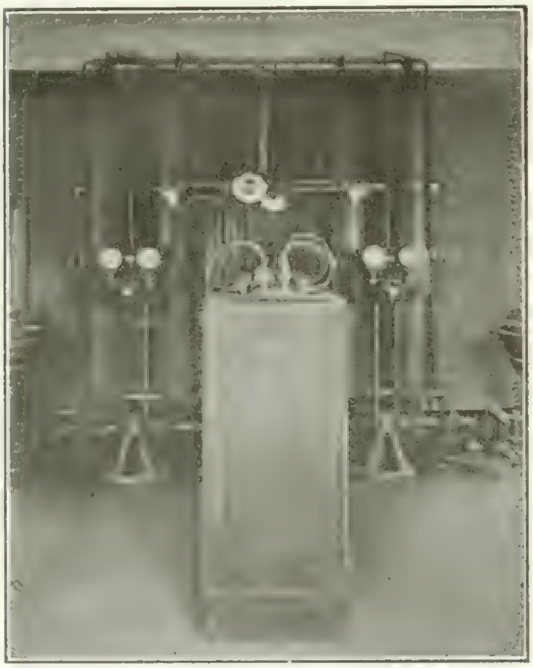


Fig. 3.—Torresdale Liquid Chlorine Plant.

(2) As to the saving in space required, a 100-lb. cylinder occupies 64 sq. in. floor space. A stock for 50 days at 200 lbs. a day would occupy a space of 45 sq. ft., 5 ft. high. About 20,000 lbs. of bleach, enough for but 17 days at 1,200 per day, would occupy (taking the can at 750 lbs. each) 160 sq. ft. On a basis of 6 to 1 about 10 to 11 times as much space is required for bleach as for liquid chlorine.

(3) With efficient controlling devices liquid chlorine will eliminate the disagreeable odors and corrosive influences of chloride of lime; consequently the installation may be placed in position where the use of chloride of lime is impossible. Ordinarily this is true. The odor of chlorine at Torresdale is hardly noticeable; but there are times when, due to carelessness or accidents, the atmosphere has been unbearable and chlorine has escaped in large amounts. (This has usually been caused by the failure of the water supply used for absorption and not by the apparatus.)

(4) Liquid chlorine will retain its full efficiency over unlimited time, whereas chloride of lime deteriorates rapidly. This is one of the best arguments for liquid chlorine, especially for small installations.

(5) The floor space occupied by liquid chlorine plants is small, whereas chloride of lime installations require large mixing tanks, etc. The space occupied at Torresdale for bleach treatment, independent of the space for weighing, was 22 x 16 ft. For the liquid chlorine apparatus the cabinet is 2 x 4.4 ft., and the space occupied by the towers is 10 x 2 ft.

(6) The reaction with liquid chlorine is simple, while that with chloride of lime is complex and less effective at low temperature.

(7) According to Dr. D. Jackson, 1 lb. liquid chlorine equals 9 lb. chloride of lime. According to J. A. Kienle it equals 8 lb. Theoretically, it should equal about 3 lb., but in practice considerable available chlorine is lost and the theoretical amount is nearer 1:4.

Huy, at Niagara Falls, claims to get as good results with 3 lb. of liquid chlorine per day with 6,000,000 gal. of water as he did with 30 lb. of powder. He added 30 lb. to the filter effluent. He adds 9 lb. liquid to the water in the sedimentation basin and 3 lb. to the effluent of the filters. The results are not quite comparable. At Torresdale, liquid chlorine is being used at the rate of about 1:6 to 1:7. It is quite possible that with careless handling and storing of bleach at small plants the figure is nearer 1:8 than 1:6.

(8) No taste or odor appears in water treated with liquid chlorine. Major Darnell states that at least two parts of liquid chlorine, equivalent to 16 lb. per million gal., must be used to give the slightest taste to Potomac River water. Huy stated that when using 5 lb. per million gal. a slight taste was noticed in the laboratory directly after dosing. On a test at Middletown, Conn., 14 lb. per million gal. were used without its being noticed. It is quite possible that if the dosage is heavy enough the water will have a taste, but figuring on a basis of 6:1, 30 lb. of chloride of lime would be needed to correspond to Huy's 5 lb. and 80 lb. to the amount mentioned by Darnell. From a close examination of the literature on

Comparative Results of Treatment With Bleach and Liquid Chlorine at Torresdale.

Date.	Treatment per million gallons.	—Bacteria per cu. cm.— Applied.	Filt.	Treated.	Per cent. removed.	—B. coli in— 1 cu.cm.	10 cu.cm.
Feb. 22-March 31, 1912	9-lb. bleach	17,000	760	260	64	2	13

*Per day.

chloride of lime and from personal observation, the amount of chloride of lime that will give a taste to water may be estimated at from 7 to 20 lb. per million gal., the average figure being from 10 to 12.

(9) Liquid chlorine does not change the character or the water by the introduction of lime salts. The lime salts will usually amount to not over one part per million.

(10) Liquid chlorine necessitates no labor cost while chloride of lime does. This is true, but a liquid chlorine requires skilled supervision to be operated properly and is not fool-proof.

(11) Liquid chlorine leaves no sludge.

(12) Liquid chlorine will reduce the amount of alum needed for bacterial removal. There can be no question but that in cases where the water is comparatively clear and where alum is used chiefly for bacteria removal if liquid chlorine is used before filtration it will make a marked saving in the cost of alum and in many cases will not only pay for itself but will decrease the general cost of the plant.

A saving of ½ grain per gal. of alum at 1c. per lb. by the use of 1 lb. liquid chlorine per million gal. at 10c. means a saving of 61c. per million gal.

(13) The feed of liquid chlorine is regular from hour to hour while the feed of chloride of lime varies constantly.

Objections to Use of Liquid Chlorine.—The chief objection to the use of liquid chlorine lies in the concentrated energy of the material itself. If liquid chlorine is set free in small enclosures it will cause nausea. With ordinary common sense and judgment on the part of the operator this is not likely to happen. The greatest danger lies in faulty cylinders and faulty valves. If the cylinder valve will not turn off or if the cylinder leaks it must be gotten out to the open air and the chlorine allowed to escape. Careful inspections of cylinders and valves must be made.

When it comes in contact with moisture, liquid chlorine has a very corrosive action, but this has been overcome by the use of hard rubber pipes and towers.

Comparative Costs.—The following estimated comparative figures are submitted:

Chloride of lime costs us from $1.22 to $1.70 per 100 lb.; the usual quotation was $1.34 and the average figure $1.40. We used during 1913 an average of a little over 1,200 lb. a day, or $16.80 a day for powder. Two laborers at 25c. per hour were employed for eight haurs, making a total cost of $20.80 per day, exclusive of repairs, sample collecting, or laboratory analyses.

180 lb. of liquid chlorine would cost, at 10c. per lb., $18 per day. We have now passed the worst conditions of the year, February and March, when we used 234 lb. a day or $23.40 cost. It is expected that we will be able to reduce the amount of liquid chlorine to at least ¾ lb. per million, or 120 lb. a day.

Some supervision and handling of cylinders is required. At present the work is done by a $3 a day mechanic, who also keeps the pre-filters in repair. His wages is charged against the pre-filters. A charge of $1 per day would be fair for this service. This is partly balanced by the discontinuance of laboratory analyses.

The labor cost during 1913 of $4 per day at Torresdale, with its output of 180,000,000 gal., amounted to but 2.2c. per million gal. At Belmont and at Queen Lane the labor cost of about $1.50 per day amounted to 3.8c and 3c. respectively. At Roxborough plants the labor cost averaged over $1 per day for mixing, that at Lower Roxborough cost 10c. per million, and at Upper Roxborough 6.7c. per million. The cost per million gallons at these plants during 1913 amounted to from 16 to 18c. At 1 lb. per million gal. for liquid chlorine the cost would be 10c., or a saving of 6.8c. per million gal. On April 14th the quantity used was reduced to ½ lb. per million gal., or a cost of 5c., a saving of from 11 to 13c.

Belmont and Queen Lane are saving a labor cost of 3.8 and 3c. Belmont is operating at a rate of ½ lb. and Queen Lane at ¾ lb., or about 5 and 7.5c.

In general, the cost of the two processes should be about equal, but liquid chlorine should prove the cheaper of the two.

With the use of liquid chlorine it is necessary to have an accurate determination of the flow of gas; it must be kept in a condition that it will not corrode the apparatus, and a proper absorption of the gas must be obtained. This has been accomplished by the use of absorption towers, which require from 50 to 100 gal. of water per 1 lb. of chlorine used.

While in some instances liquid chlorine may prove more costly than chloride of lime, the regularity with which it can be applied, the more effective the action on pathogenic bacteria, the small compact apparatus and the absence of the odor of chlorine around the plant recommends it as a satisfactory substitute for hypochlorite, possessing as it does all the advantages of the latter and only some of the faults.

It has been shown from experiments conducted in Belgium with a view to discovering the effect of foreign metals on the rolling of zinc, that ingots weighing 40 lb. were prepared by casting together zinc alloys of various metals, with spelter containing lead 1.05 to 1.25, cadmium 0.076 to 0.11, and iron 0.03 to 0.039 per cent. It was found that cadmium is harmful above 0.25 per cent., while with 0.5 per cent. rolling is impossible. In regard to arsenic, 0.02 per cent. markedly increases the hardness, and with 0.03 per cent. the metal is too brittle for practical purposes. Antimony is less objectionable than arsenic as regards hardness, as 0.07 per cent. does not increase the hardness; but 0.02 per cent. is enough to produce a striated surface on the rolled sheet, which makes it unsaleable. Tin is objectionable when above 0.01, and prohibitive at 0.03 per cent. Copper has no hardening effect until it reaches 0.08, and with 0.19 per cent. the zinc is unworkable. A permissible maximum of iron is 0.12 per cent., but this is easily reduced in refining. Though 1 to 1.25 per cent. of lead does not interfere with the rolling, a slight increase not only seriously affects malleability, but the excess of lead remains unalloyed and forms patches on the sheet. The presence of two or more impurities together results in a combination of the injurious effects of each.

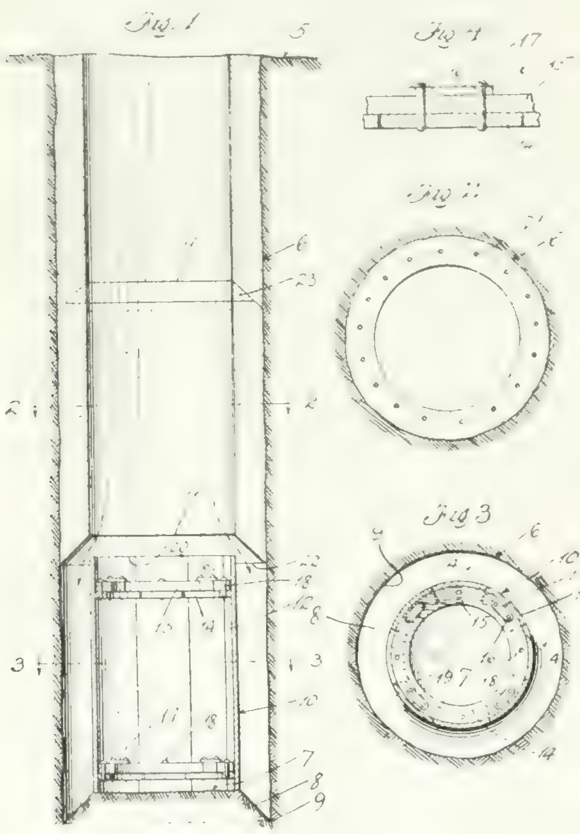
"Le Genie Civil" reports the results of tests made at the Ecole Centrale, Paris, to show that when holes are drilled and then reamed in soft-steel bars the metal materially increases in strength, the average limit of elasticity improving 12.3 per cent. and the average tensile strength 9.2 per cent. This phenomenon is explained thus:—In putting together the parts of a test piece broken under tension, it is found that the two ends do not coincide; and that, while the edges make a good contact, the central parts do not, thus indicating that the rupture begins at the centre, and that the edges have a higher tensile resistance than there is along the axis of the bar. Therefore, if several holes are drilled so as not to injure the material too much, as might be the case with punching, the average tensile strength of the section across the holes, per unit of metal, will be higher than before the holes were drilled, since each hole creates, so to speak, additional edges.

METHOD OF LINING CONCRETE SHAFTS.

A PATENT recently issued in the United States (No. 1089573) relates to a method of lining shafts with concrete, the principal object being to provide a method to eliminate the building of elaborate retaining walls in a well shaft. It is also an object to provide a method by which the concrete may be inserted in sections progressively from the top or ground level downward.

Fig. 1 is a central longitudinal section of a shaft showing two of the sections of concrete introduced, and the form in position ready to place the next succeeding section of the lining. Fig. 2 is a cross-section on the line 2—2 of Fig. 1, viewed in the direction indicated by the arrows. Fig. 3 is a cross-section of the shaft on the line 3—3 of Fig. 1, viewed in the direction indicated by the arrows. Fig. 4 is a detail section on the line 4—4 of Fig. 3, viewed in the direction indicated by the arrows.

Heretofore in the lining of shafts with concrete the shaft has first been sunk or dug the required depth, requiring a temporary lining to retain the walls of the shaft intact and prevent caving in upon the operators. Then this supporting lining either has to be removed or become a loss by being left in the shaft while the forms are inserted and the lining introduced from the bottom upward, the entrance of water in the lower end of the shaft or intermediate positions complicating this process.



This invention overcomes the above difficulties by providing a method by which the shaft is enclosed with the permanent lining as the work progresses downward without great delay, and materially reducing the cost and increasing the efficiency of the structure.

In the drawing, numerals are used to designate the same parts in the different views, 5 designating the surface of the ground, and 6 the shaft vertically dug therein by any suitable means or apparatus, the method preferably used being to dig the shaft a depth equal to the height of the collapsible form preferably used. In practice this form is about 6 ft. in length, depending on the character of the soil through which the shaft is being sunk. The section dug is preferably as indicated, in the lower portion of Fig. 1, so as to provide the platform 7 of a diameter equal to the diameter of the finished shaft, from this point downwardly and outwardly, being excavated to leave the inclined face 8 until the concentric periphery of the major diameter of the shaft is met at the point 9. On this platform 7 the collapsible form 10 is erected, the upper edge of which falls slightly below the inner edge 11 of a previously formed section. The form 10 is preferably formed of a plurality of vertical sections 12 each of which is provided with a flange 14 secured thereto at suitable distances, the flanges, when various sections are placed adjacent one to another, abutting to form the circular configuration or cylinder, upon which flanges are supported the 4 sections of the rim 15, which are held together by suitable means, as pins 16 passed through the locking plate 17 together with the pins 18, which pass through the flanges 14 and the rim 15 intermediate of the locking plates 17. One of these sections is necessarily cut away as indicated in dotted lines at 19 so that this section may be removed to allow the collapse of the form after the concrete has been inserted.

As before stated, the concrete is introduced between the upper edge 20 of the form and the lower inner edge 11 of the previously formed section of the concrete lining, which is preferably reinforced by the vertical rods 21 supported in any well known manner. This upper edge 20 preferably extends a slight distance above the lower edge 22 of the last section of the concrete lining.

The shaft is preferably dug during the day the required depth, then the process of tamping the concrete lining in place is performed, and the concrete left to cure over night, while the man is otherwise occupied. The concrete sufficiently sets to permit the removal of the forms the next morning, and the shaft is sunk the corresponding distance only limited by the length of the form used. The triangular space 23 is filled either before the removal of the form and troweled in position, or inserted afterwards, as may be found preferable.

In an excavation having a lining of this character, the cost over usual constructions has been reduced approximately one-half, together with the material increase in speed of construction, and with greater assurances of safety, the irregular portions of the shaft walls firmly grasping the concrete sections, and preventing sliding as well as the connection to one another by adhesion, or suitable connections between the reinforcing rods.

The method is described to considerable length in "The Mining World" of recent date. Mr. Edward Morlae is the inventor.

A very notable feature of the recent convention of the American Water Works Association was the devoting of an entire day to the interests of the superintendents and others closely associated with the operation and maintenance of waterworks. The morning and afternoon sessions were devoted to the discussion of subjects introduced in the printed "question box" of the association. These subjects, dealing chiefly with water meters, dwelt upon such points as their setting, testing, design, maintenance and repair. Superintendent's day turned out to be a very important one for those dealing with the practical rather than the scientific phases of such work.

Editorial

CONSULTING ENGINEERS AND MUNICIPALITIES.

One regrettable feature of the whole attitude of the public to the engineering profession is that it is the layman himself who has produced the circumstances to which this not overly healthy attitude is to be attributed. So long as he allows political and personal influences to interfere in the selection of engineering assistance, and in the disposition of experts' reports, engineering will not be regarded by the man of the street as belonging to a plane any higher than it is now. Rather than maintaining the title of profession, argument is not lacking in instances where it is so unfortunate as to be lower in repute than the union-protected trades which follow in its wake.

Take, as an example, the consulting engineer—the highest type of which engineering can boast—the profession department as distinguished from the practice. A municipality has before it a project with an engineering problem attached. A consulting expert is called in to make a report upon what engineering it entails and its estimated costs of construction and operation. He gives it a thorough study, wherein his technical training and ability unite with his practical experience, grown out of a series of similar problems during his career, and are applied to the local conditions and requirements. He submits his report, presents his bill, receives his fee, and the transaction is closed. The municipality sought expert advice, got it, paid for it. The solution of the problem is before the peoples' administration board. The next step is to go ahead with the development.

But how prone Canadian civic officials are to question the value of the technical services they have purchased. The plans may fail to suit the inclinations of an aldermanic official or two, and if the influence from this quarter is sufficient the report is sidetracked and the question lies dormant while ratepayers are expecting daily to hear the sound of pick and shovel. Eventually the problem is revived, and another consultant is called. Obviously, he understands that the previous report was unsatisfactory, and that his scheme must have a different basis.

Thus, besides a split in administrative ranks, there are added expenditures, and delays in getting the development under way. There is also a depreciatory effect upon the engineering profession in the minds of the ratepayers, besides a tendency toward breaches of professionalism among engineers themselves.

So many instances of the above state of affairs have developed during the past few years that one may safely acknowledge it a serious detriment to the development of the country and to the welfare of the engineering profession. In many of our towns and cities the application of expert engineering advice to the problems of the day has been shamefully manhandled.

If civic officials are fearful of encountering incompetency in retaining such services and are afterwards dubious of placing dependence upon the advice, whatever it may be, they should not be slow to realize that in the engineering profession itself rests a reliable safeguard against mistakes. The condition is not unlike a transitory stage in the history of England, not so many years removed as to be incomparable. For upwards of a century municipal problems were often subjected to incompetency at the hands of would-be engineers who did not hesitate to attack any problem for a cut-rate fee, and whose schemes frequently resulted in enormous useless expenditures on construction of works which necessitated abandonment after a short period of unsuccessful operation. The establishment of the Local Government Board, equipped with an engineering department whose duties included the thorough examination of every scheme, has resulted in a cessation of such unfortunate occurrences and eliminated the engineering-adventurer.

Canada, with her formidable array of engineering problems, might well establish a similar institution for the purpose of checking risk and excessive expenditure in the engineering work of her municipalities. It should be necessary for every scheme to pass muster, in the minute and exhaustive inspection of a board of officials comprising the best engineering talent in the country. Millions of dollars would be saved; delays, detrimental to the health and comfort of the people, would be dispensed with, and engineers would encounter a more optimistic and encouraging tone among their fellow-men.

Such a board would deal with reports, rejecting or approving of them as their quality merited, and let the city councils choose whom they might as a consultant, his report upon the proposed development would have to depend entirely on its merits.

POWER DEVELOPMENT ON ST. MARY'S RIVER.

Occasional reference has been made in these columns to the work of the International Joint Commission, and to the questions which have at various times been presented to it by the Canadian and United States Governments, since its inception in 1909. The most recent findings of the Commission have been in connection with the applications of the Algoma Steel Corporation, Limited, and the Michigan Northern Power Company for the diversion of water for power purposes and the construction of compensating works in the St. Mary's River at Sault Ste. Marie.

After approximately twenty months of investigation official approval was given in Ottawa last week for the diversion of about 30,000 cubic feet per second on either side.

The primary importance of conserving the present conditions for navigation was evidently the chief contending factor in the extended investigation. Shipping interests on the Great Lakes commanded practically no molestation in the St. Mary's River. With this in mind, the recent judgment is found to possess significant features in the interests of navigation. The diversion for power purposes is contingent upon the erection of sixteen sluice gates across the river to compensate for it. These sluice gates are to be under the absolute control of an international board composed of two engineers representing the governments, and whose duty it will be to maintain Lake Superior at a level best suited to navigation and to the various communities along its shores.

LETTERS TO THE EDITOR.

"Road Building Economics."

Sir,—The writer has read the paper entitled "Road Building Economics," by Mr. Reginald Trautschold, M.E., in your issue of May 14th, but takes exception to some of the author's statements in regard to asphalt paved streets.

The subject "Asphalt Paved Streets" is, to begin with, quite vague, for there are several types of asphalt paving in use to-day and their variations in cost and life are too great to be covered by a single formula. It is presumed, however, that the author refers to the standard sheet asphalt construction consisting of concrete base, binder course and wearing surface.

Mr. Trautschold states that

> "The softening of the paving surface, if subjected to even the summer temperature of many localities, limits the use of this class of roads to cities in the temperate zone, in even which localities the softening of the asphalt surface has much to do with the very high maintenance charge. . . . ."

This statement is indeed a surprise, for it is now well known that such softening, as well as cracking with cold, can be to a great extent taken care of by properly designing the paving mixture.

Asphalt cement, the binding medium, is not a material of fixed characteristics and the engineer has at his disposal not only the various consistencies but the different brands of bituminous materials as well. If he is properly advised as to this feature and the mineral aggregate is properly selected and graded, there is no reason why the sheet asphalt pavement should not be successful even in greater extremes of temperature than now employed. It is noiseless, sanitary and can withstand the heaviest traffic, as is shown by the fact that it is to-day replacing the old stone pavements hitherto considered necessary in business districts.

Your author's formula must certainly be founded upon inferior construction for, with proper materials and supervisions, the life of the sheet asphalt pavement should be considerably over ten years. I quote, for instance, the following statement from the Report of the Engineer Commissioner of the District of Columbia for the year ended June 30th, 1909:

> "Many of the asphalt pavements . . . have been down for from 20 to 37 years, and . . . about 20 years represent the effective and economical life of such pavement."

The District of Columbia was the pioneer in asphalt paving construction and, with its data 40 years' experience, the above testimony would seem most competent. Furthermore, the science has progressed considerably in the five years since the report was written.

A study of these facts and the present competition in bituminous materials will serve to reduce Mr. Trautschold's cost and maintenance charges and show this type of pavement to have, after all, an individual economic value.

LEROY M. LAW.

Baltimore, Md., June 2nd, 1914.

"Determination of Areas of Cross-sections."

Sir,—In your issue of March 12th, 1914, there appears an article by Mr. C. D. Norton entitled "A Method of Determining the Area of Cross-sections." It is a singular coincidence, but the method in question is almost identical with one worked out by the writer over a year ago now, and which early in February, 1914, in the form of a booklet, was published and copyrighted both in Canada and the United States.

A copy of the booklet for your information is sent herewith, and those interested will also find a resumé of the subject matter in it in "Engineering News," issue of May 28, 1914.

Mr. Norton, however, in his article, does not show that it is quite unnecessary to ascertain the actual cuts or fills at the various points on the cross-section for the rod readings as taken, at these points, with far less labor and with less liability to error, can quite as well be used. In the writer's opinion this very point is of vital importance when considering the method from the point of view of a time-saving device.

For instance, on page 6 of the booklet, the information there given for each particular section, of necessity, must be obtained in the field and noted in the level book in one form or another.

In order to obtain the area of the section, however, as it happens, nothing more is required; the very figures given there are used in the calculation. In plain language, each horizontal distance to a point has been multiplied by the difference between the rod readings of the points coming immediately after and before such point, one-half the sum of such multiplications giving the total end area of the sections.

While at first sight the above might appear slightly complicated, it will be found that in practice, once one has become familiar with it, the whole operation is an exceedingly simple one. The difference in the rod readings can usually be obtained mentally and jotted down directly on one page of the level book with corresponding horizontal distance, where at any subsequent time such figures and resulting end areas can very easily be checked by an assistant.

It is the intention to have the booklet mentioned above bound up with other tables in the front of the ordinary blank level book, where, whenever required, the method will be available to all who desire to save time by using it. The cost of the level book to the engineer will not, of course, be increased by this insertion.

E. S. M. LOVELACE,
Consulting Civil Engineer.

Montreal, June 5th, 1914.

It has been reported from Cordova, Alaska, that actual work on the survey of possible routes for the government's railway in Alaska was begun on June 2, when the first stake was driven at Chitana by a reconnaisance party under Henry Deyer, who will survey the route from Chitana, where the Fairbanks railroad leaves Copper River and Northwestern railway to the coal field.

Capitalists of Yokohama are engaged upon the preparation of plans for the construction of a dock at Namamugi, a suburb of Yokohama. According to the plans 344,134 tsubo of water front will be reclaimed and divided into four divisions. The first division will be used for docks, the second for shipbuilding and on the third and fourth several houses will be built. It has been estimated that the expenditure will be Y.2,234,000, and the work is expected to be completed in 5 years.

BULKLEY RIVER BRIDGE, BRITISH COLUMBIA.

Across the Bulkley River at Hagwilgate, near New Hazelton, B.C., has been erected a single span suspension bridge which ranks among the highest of its type in existence, being 250 ft. above the water level. The span is provided with stiffening girders to curtail vibratory and undulating movements under traffic and wind. It is the first of its kind, according to the builders, Messrs. Geo. Cradock & Co., wire rope manufacturers and engineers, of Wakefield, England, to be hung from catenaries of locked coil cables, the latter being claimed not to rotate or lengthen.

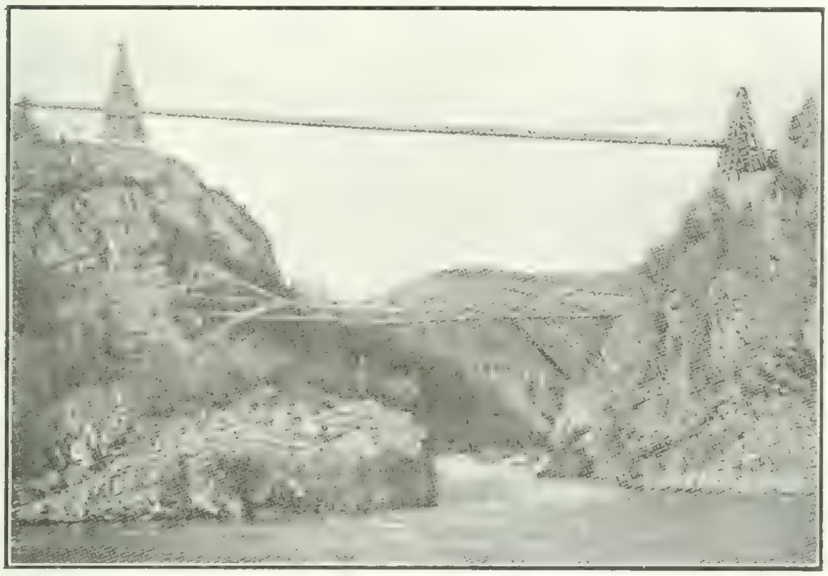


Fig. 1.—View of Bulkley River Suspension Bridge.

Fig. 2.—View of the Structure from One of the Approaches.

It spans the Bulkley River at a point where it is confined between the walls of a rugged canyon, as shown in Fig. 1. The span itself is 451 ft. in length, the whole structure being over 600 ft. in length when approaches are included, with a roadway 9 ft. in width. The bridge is suspended from timber towers 65½ ft. high, one of which has been mounted upon the solid rock, while the other is furnished with a concrete pier foundation. The cables, 2½ in. in diameter, are each anchored by 3-in. steel bolts embedded in concrete blocks approximately 15 x 20 ft. in dimension. The suspension rods are ¾ of an inch in diameter, and are clamped to the suspension cable at the top, while the bottoms are thickened to ⅞ of an inch and threaded. These rods are placed 4 ft. apart on either side and carry the floor beams, also 4 ft. centre to centre, diagonally braced. These floor beams support 4 x 7-in. stringers, upon which is laid the floor of the bridge consisting of 3 x 4-in. plank. The timber is all of British Columbia fir. Over 50 tons of steel have been used in the construction of the bridge. The coiled locked cable has a tensile strength of 350 tons and the bridge itself is designed to safely carry a rolling load of 18,000 lbs.

The stiffening steel girders forming the sides of the bridge are of lattice type and extend from the floor to the hand-rail.

The contract for the construction of the bridge was awarded in 1912, but owing to the severity of the winter in northern British Columbia no work was attempted before the spring of 1913, whereupon Mr. Percy Cradock, one of the directors of the firm, took charge of the construction. The entire structure was completed in the course of two months after the foundations had been built. Fig. 3 illustrates the hazardous construction work associated with it.

The work was carried out for the New Hazelton Bridge and Power Co., and accommodates the vehicular and pedestrian traffic of the Bulkley valley.

Fig. 3.—Bulkley River Bridge in Early Stage of Construction.

Fig. 1 also shows an old structure which has been used for years as a means of transportation across the river. It was built by Indians and is in striking contrast to the new structure suspended above it. The members of the old Indian structure are held together by wooden pegs, no nails having been used in it.

ROAD IMPROVEMENT COMPETITION IN SASKATCHEWAN.

The annual road drag competition established last year by the Highway Commission of Saskatchewan started on June 1st and will be continued through June, July, August and September. In the early part of October all competing roads will be inspected simultaneously and the prizes awarded according to the points earned during the period of dragging.

THE BULK HANDLING OF CEMENT.*

By H. M. Capron,
President of Marsh-Capron Mfg. Co., Chicago, Ill.

THE use of cement in bulk is comparatively new. The writer's interest and experience with bulk cement started with the mechanical problems involved in handling and storing the cement and other aggregates at the mixing plant, the measuring and conveying them to the mixer, and the mixing and handling of concrete.

Some of the large cement companies, and a few progressive contractors have recently been studying this problem. Like all new ideas, however, its beneficiaries accept it reluctantly, and its advocates are subject to the criticism and ridicule which greets all pioneers.

It is a remarkable commentary on human nature that the people who are to be benefited by a new idea are the slowest to adopt it: and it is equally significant that once a contractor has used bulk cement, he becomes one of its most enthusiastic converts.

It requires no little originality, and a great deal of courage to depart from a custom of years' standing in any line of business, and such departure must of necessity be founded upon logic which is absolutely sound.

Ever since Portland cement became a factor in the contracting business it has been delivered to the ultimate consumer in packages. At first wooden barrels were used, but they were so cumbersome and difficult to handle that a small package was substituted, and now cement is handled almost universally in cloth sacks, or paper bags, four of them constituting the commercial unit, the barrel.

Cement is only one of the component parts of concrete. The fine and coarse aggregates—sand, gravel and stone—have always been handled in bulk, and an inquiring mind uninfluenced by business custom would naturally ask, "Why should cement be delivered in packages when the other aggregates are always used in bulk?" Careful consideration of the subject showed many reasons why cement packages could, and should, be eliminated from a great many classes of concrete work, and to demonstrate the practicability of this new idea, the originators presented it to certain contractors for their favorable consideration, which was at last secured.

The present age is one essentially of conservation, not of conservatism, and if it can be satisfactorily shown that there is an economic waste in packing cement in sacks only to reduce it to the bulk condition before it can be used, the attention of every contractor who must necessarily pay for this packing and unpacking of cement is immediately challenged. If the contractor can be relieved of this expense and can at the same time purchase his cement for a smaller figure, it is obvious that there will be larger margin of profit for him in his work, and those who adopt this method first will have the greatest advantage over their competitors.

The cement company which developed this idea offers cement in bulk for 42 cents per barrel less than the price of cement in cloth sacks. Forty cents of this is, of course, represented by the cloth sacks themselves, and two cents represents the saving to the cement company in packing and loading cement in bulk. Therefore, as far as the manufacturer is concerned, the only saving in this method is in elimination of the cloth sacks which would otherwise be used. This, of course, relieves the manufacturer of the cost of counting, inspecting, cleaning, and repairing these sacks when they are returned to the mill by the contractor for credit. On the other hand, new machinery is necessary to load and weigh bulk cement when it is placed in cars. A device called a weightometer has been adapted for this purpose. This machine consists of a belt upon which the cement is conveyed into the car. This belt passes through the weightometer and all the cement on it is automatically weighed and recorded by the machine, so that the operator can tell by a glance at the dial exactly how many pounds of cement have passed through the machine into the car. A car of bulk cement, therefore, in being loaded, is weighed as a unit. When it is loaded, figuring as is done in the United States, 376 pounds to the barrel of cement, and assuming that the car is to contain 250 barrels, the belt is stopped when the dial registers 94,000 pounds, and the entire car is thus weighed in one operation. If the same car is loaded with cement in cloth sacks, 1,000 sacks would be required, and likewise the necessity of weighing 1,000 separate objects. Thus the liability of error in weighing is reduced from 1,000 chances to one. It is, of course, the object of every honest manufacturer of cement to furnish correct weight, and cement in bulk represents the most satisfactory way of doing this.

Some doubt may be raised as to the difficulty in protecting the cement from moisture, both in transit from the mill and at the mixing plant, but this has proved to be purely theoretical.

The damage to bulk cement in transit by reason of a leaky car is by actual experiment shown to be 50% of the damage the same amount of water would inflict if falling on cement in cloth sacks. The reason for this is that when water comes in contact with the cotton cloth, by capillary attraction it spreads to the adjacent sacks so that a leak in a car roof will frequently ruin a whole tier of sacks from top to bottom of the car, and damage a large part of the cement contained in these sacks. If water falls on bulk cement it is absorbed immediately where it falls and the resulting damage consists of a crust of cement depending in size on the amount of water, and the damage is confined to the spot immediately under the leak, and all the damaged cement can be lifted from the car in this cake.

Experience has shown that the handling of bulk cement does not raise as much dust as cement in cloth sacks. The cement sifts through the sacks with the many handlings so the natural cohesion between the particles is broken and the dust is blown away or falls off. The method of handling it in bulk saves all this waste. The method of handling, of course, varies with the physical conditions surrounding the work.

In the early stages of the development of bulk cement shipment, the material was handled successfully and in large quantities by contractors who did not spend a single cent on special equipment. They reasoned that if they could handle and measure the sand and stone (which is 90% of the concrete job) by means of wheelbarrows, they could handle and measure the 10% of cement that it would require, with equal accuracy and facility. A great many jobs of considerable magnitude are still being carried on in this way, but naturally the possibilities of bulk cement in saving labor and increasing the output of a concreting plant may be more fully realized by means of equipment more particularly adapted to the work. When the work is adjacent to a railroad track and the size of the job warrants it, a bin may be constructed

*[illegible] at the First Canadian and International Good [illegible] Congress in Montreal, May [illegible], 1914.

alongside the track into which the bulk cement is conveyed by means of the bucket elevator. On one side of this bin is built a hopper for the coarse aggregate, and on the other side one for the fine aggregate. Both of these aggregates feed from the bottom of their respective hoppers, through spouts, into the mixer hopper. Experience has shown that a non-tilting type of concrete mixer lends itself best to a plant of this kind, as it requires less head room. These aggregates are handled from the cars into these hoppers by a clam-shell operated by a standard hoisting engine or by the same bucket elevator used in elevating the cement.

The bulk cement is moved from the car by a scraper similar to that used for unloading grain. With this the cement is scraped from the door of the car into the chute which feeds into the bottom of the elevator leg. From the bin the cement falls by gravity through a measuring box into the mixer hopper. Thus we see that the only labor connected with delivering the cement into the mixer is that required to unload the car with the device above described. Two men in one hour can easily unload a car containing 250 barrels of cement in bulk. By this method the contractor is saved the cost of the labor which otherwise would be necessary to perform the following activities:—

1. Carry the cement, sack by sack, from the car to the storage shed, and pile in shed.

2. Carry the cement, sack by sack, from the storage shed to the mixer platform.

3. Untie each sack and empty the cement, sack by sack, into the mixer hopper.

4. Shake out the empty sacks over the mixer-hopper to relieve them of all their contents.

5. Lay the sacks aside to be bundled.

6. Bundle the empty sacks for shipment to the mill.

7. Remove the bundles of empty sacks to the storage shed to await the accumulation of a shipment.

8. Load the bundles of empty sacks into a car for shipment to the mill, prepaying the freight on them. Then ensues a long wait while the sacks go to the mill, and are counted and inspected there before a credit can be issued on them and a cheque sent to the contractor for the value of the good sacks found in the shipment.

In every one of these eight stages the sacks are liable to damage by abuse of careless workmen, by exposure to the weather, and in many other ways. Sacks also make convenient aprons for workmen, tool bags, cushions for drivers to sit on, and it is reported that even shirts made of cement sack are stylish among some workmen. The loss on a job of this kind in all of its many phases, is variously estimated by contractors at from five to ten cents per barrel on the amount of cement used.

Every contractor who handles Portland cement recognizes that the empty cement sack is the most fruitful source of dispute with the manufacturer, of loss on the job, and of general inconvenience in handling cement. Everyone will instantly recognize that the elimination of the sack on the job would be a great boon. If, besides securing the advantages incident to removing the sack entirely from the work, the contractor finds himself relieved of a large item for labor in handling these sacks, both full and empty, there is no question that his best interests demand that he use cement in bulk wherever feasible. Where the mixing plant is removed from the railroad track 100 ft. or more, belt conveyers have been used to take the cement from the car to the elevator connected with the overhead bin. The fine and coarse aggregates may be handled over the same belt into bins provided for them, so that the gravity-feed into the mixer hopper can be applied to all of the materials going into the mixer. The number of laborers saved by this kind of an arrangement varies with the magnitude of the job and in any case the saving well repays the contractor for the installation of the necessary handling machinery and for the construction of these overhead bins. But, as already stated, the physical conditions of each job will require an arrangement best suited for its individual need. Cement in bulk takes up less room on the job, which is sometimes very desirable. Take as an illustration a large paving job which came to the writer's attention recently. This job requires 30,000 barrels of cement which means 120,000 sacks. At 10 cents per sack it takes $12,000 more to finance the job than if the cement were delivered in bulk. This bag money is tied up until credit is received from the manufacturer for sacks returned and every contractor knows how long it takes to get this credit.

Figure the average loss of sacks and interest on money invested in this case as 10 cents per barrel, or $3,000 actual loss, to say nothing of extra labor required in handling all these sacks; in any case the amount of capital necessary to finance the job is materially reduced.

It is quite evident that this subject is worthy of study by all contractors on large work.

TOWN PLANNING.

"Conservation," issued monthly by the Conservation Commission of Canada, makes the following statements and definitions about the subject of town planning:

It is the selection of the site and environment, and the adaptation of the same for settlement by an intelligent method, having in view health, amenity and convenience.

It is not a fad, but simply an orderly method of doing what must be done in any case.

It means life for the babies, and better health for each person in the town.

It assures to mothers and children as healthful homes and home environment as the factory act provides healthy workshops for mechanics.

It supplies suitable streets for all sections, whether residential or industrial.

It provides for cheap and rapid transportation.

It gives the children playgrounds in lieu of dusty streets and dirty lanes.

It prevents the undue encroachment of business upon residential areas.

It allocates to factories their proper place.

It is an important factor in giving a higher morality to the people.

It bestows on the many advantages at present only possible to the few, giving to the poor blessings denied them under existing methods.

It pays, because it is of economic value to the municipality permitting it to acquire property, which is sure to enhance in value at a minimum of cost.

It is what all should work and strive for, ennobles citizenship and elevates the nation.

The 1914 convention committee of the American Electric Railway Association, acting with the committee of the American Electric Railway Manufacturers' Association, has decided upon Atlantic City as the location for the 1914 convention. The dates are October 12 to 16.

FACTORS IN ROAD ECONOMY.*

By Will P. Blair,
Secretary, National Paving Brick Manufacturers' Association, Cleveland, O.

WHAT is the economic value of a road? By what shall it be measured? Shall it be measured by comparison with other roads or with roads built of other materials, or shall it be reckoned upon its own merits separate and apart from any comparison? Comparisons are said to be odious and are therefore interpreted as coming within a class of criticism that to some seems objectionable. The writer sometimes thinks, however, that the relative merit of paving material ought to be brought out by the sharpest kind of contrast. Unquestionably in the discussion of pavements and their worth, had they heretofore been considered in such meetings as this and through the columns of papers that are devoted to road and street building upon their relative worth, the public would by this time have been saved thousands of dollars. Much of the money that has been wasted in experiments would have been saved by the force and influence of a discriminating reason and sound judgment.

If a paving material possesses worth, the time has come when the public should know it; if unworthy in any way, the truth is worth more now than a season of repenting.

There are involved in the economy of a road: Its first cost; its use, and its up-keep. These elements of economy bear a close and distinct relation to each other. Each must sustain a harmony of relationship with all combined. The cost, therefore, must be commensurate with its use and its use must be sufficient to justify its up-keep. Its up-keep must be within bounds justifying its maintenance.

There are other elements in the matter of road economy that must be considered. The effect of the road itself upon abutting property, whether detrimental or injurious. The effect upon its users in a way that pertains to their comfort and pleasure.

Whether or not the time has come when the official charged with responsibility shall assert his professional judgment; whether the time has come when data that ought to constitute the basis of that judgment will be supplied and used both as to the grade quality of the improvement and the uses to which it may be subjected, is doubtless a question, because neither is done. Whether all pavements that are offered to the public are established in their proper economical place or not is exceedingly doubtful.

Aside from quality, aside from cost and maintenance, local supply of that which may be used is necessarily a matter to be considered and a feature that must affect very seriously the economy of any road improvements. Good judgment, therefore, will often select a road material by the weight of such consideration that otherwise would not be chosen.

The abstract actual cost, use and maintenance cannot be applied rigidly in all cases. The economy of any road material cannot and must not be judged alone. It must be understood that it is affected by the manner and method by which that material is used in the construction of the road. But the reasonable maximum worth which is only reached by the manner and method of construction may be and should be assumed, for the reason that there is no possible excuse for constructing a road out of any material that is at all worthy of consideration in any way except that way which will render a service approaching a maximum of its possibilities. We cannot fairly approach the subject of economy of any road material except on such assumption. It will, therefore, be necessary to understand something of what is required in manner and method of construction in order to properly understand its cost.

Cost of construction and cost of repair and all else is not the full measure of economy. But the greatest element affecting the economy of any road is, strange to say, the very one that is least taken into account, and that is its out-of-repair condition. That road that calls for the most frequent repairs is the road that is most likely to be out of repair, and it is the road that in the sum of lapses of time in which it is out of repair, aggregates a total detraction from the road's worth which by the lesser load hauled, the broken spring, the injured horse, the extra wear and tear of the vehicle, if converted into dollars, would often equal in a short period of time, the entire original cost of the improvement.

When a road is out of repair, the road investment is bearing no interest. The road as a whole is only as good as its worst portion—even the rule of average will not apply. On the other hand, by inverse ratio the road approaches its maximum worth as repairs are eliminated. The road, therefore, from which repairs are practically eliminated, is the real economic road, provided only that the traffic passing over it meets in a reasonable toll charge, the interest on its cost.

This leads to the proper differentiation as to the choice of the road and the amount of its cost. The expenditure for any road is justified so long as the amount of tonnage passing over it will aggregate a toll equal to a reasonable interest charge thereon. To the extent that it exceeds such a sum, it represents a profit to the user. I may inject that in both Canada and the United States poor roads exact a larger toll than good ones should or will if we ever reach a time when our roads are intelligently built.

This continued cry for maintenance is all right, so long as it is made in good faith, but the trouble lies in the fact that behind much of it stands the father of the suggestion whose interest urges the building of a road that will need continued repair.

If we properly understand how a block stone road should be constructed, in order to attain its highest efficiency and best service, we must accord it a place, perhaps the first place, as affording the best economy for roads and streets, subject to heaviest and most severe traffic.

It is regrettable that the elements of economy that are combined in a properly constructed stone block road are known to too few road builders, and when you begin to enumerate them, many a man will regard your assertions with suspicion. The writer recalls the shock with which his assertion was received by a well-known engineer to the effect that the noise resulting from the use of a properly constructed block stone road was much less than that which was common to roads of certain other materials. The lack of appreciation in this respect was entirely due to the fact that the engineer in question had had no experience with a properly constructed block stone road.

The place here given to a block stone road will not be supported by assertions or any detail of testimony.

*Extracts from paper read at First Canadian and International Good Roads Congress, Montreal, May [illegible], 1914.

This should be done primarily by the people commercially and particularly interested in block stone pavements, and it is surprising that so far as the general public is concerned, they—the block stone people—do not understand, at least they do not advocate the best use of their own product. This concession puts the use of stone block within somewhat narrow limits, while the use of vitrified brick is properly placed within the larger limits of the excessively used highways and important thoroughfares of the country. Such roads are to be found from points where travel converges and terminates at large centres of distribution. It also includes such roads as connect up centres of trade and population—in other words, the main market roads and thoroughfares of the country.

The original cost of a brick road is not necessarily excessive. The cost of grading, drainage, bridging and the entire preparation for placing thereon the artificial foundation and wearing surface, should be alike for all types and is, therefore, no more expensive for a brick road than is required for the least expensive type of wearing surface. This necessary preparation in the case of a brick road bears a feature of economy that is well worth while to mention. It is not readily injured, either from wear or tear or from any character of climatic influences. It is likely to remain intact. With the brick wearing surface placed upon it, ample protection for the durability of all the work incident to such preparation is afforded.

A curb for a brick highway is not necessary. A small upper lug built on the extreme edge of the concrete foundation, the height of the depth of the sand cushion, is all that is necessary.

The concrete foundation, if used, must be made entirely smooth, conforming to the grade of the finished street. Even a concrete foundation is not essential in case the subgrade contains much sand and gravel, enabling a complete, ready and perfect drainage. The ideal condition is a dry subbase. A concrete foundation, however, is advisable in most instances throughout Canada where we naturally expect a considerable season of low temperature. Over this foundation, whether of natural soil or concrete, must be placed a cushion of sand to a uniform depth from 1½ to 2 inches, thoroughly and evenly compressed upon which to place the brick. The interstices of the brick must be filled from the sand cushion full and flush with the top, a mixture applied as a fluid, of the best quality of Portland cement and fine sharp sand in proportion of one to one, the setting of which shall be protected from use, uneven temperature and destructive weather elements, until completely set.

THE PROGRESS OF THE ELECTRIC FURNACE.

It has been generally supposed that British smelters and refiners have shown considerable reluctance to adopt the electric furnace, but statistics go to show that after all they have not lagged very much behind other countries. There are now 14 electric furnaces at work in England, 13 in France, 20 in Italy, 17 in the United States and 32 in Germany, besides a few in other countries, making a total for the world of something between 140 and 150. A remarkable fact is that in Germany 50 per cent. of the furnaces are of the induction type and 50 per cent. of the arc type. Out of the 20 Italian furnaces 19 are arc, as are 10 out of the total 13 French, and 13 out of the 14 English. The Heroult, the Girod, and the Stassano are the arc furnaces most numerously adopted, while the Kjellin and the Röchling-Rodenhäuser occur most frequently in the induction installations. The progress in Scandinavia is shown by the fact that Norway and Sweden employed only nine furnaces for the smelting of pig iron in 1912, and had more than doubled the number by the end of the following year, when 20 furnaces were in full operation.

TAR TREATMENT OF ROADS.

The Road Board of Great Britain has issued a second edition of directions and specifications relating to the tar treatment of roads. In the specification for tar No. 1 (suitable for the surface tarring of roads), it is stated that the distillate between 170 deg. and 270 deg. C., or 338 deg. and 518 deg. F. (middle oils), shall remain clear and free from solid matter (crystals of naphthalene, etc.) when maintained at a temperature of 30 deg. C. for half an hour. It is, however, added that "this requirement may be waived in the case of tar supplied direct from gasworks; but tar from which the naphthalene has been extracted is preferable to tar containing much naphthalene." The tar must contain not less than 12 per cent. and not more than 21 per cent. by weight of free carbon. The free carbon is to be determined by complete extraction of the bituminous matter from a weighed portion of the tar by benzol and bisulphide of carbon. The residue left on treatment with these extractives is to be taken as "free carbon." Specification for tar No. 2 (suitable for making tar macadam, and for surface tarring in very hot weather, when the road crust is exceptionally dry) stipulates that the tar may contain not more than 25 per cent. of its volume of the tar (or distillates or pitch therefrom) produced in the manufacture of carburetted water gas. The free carbon limit, which was before put at 18 per cent. of the weight of the tar, has now been altered to not less than 12 per cent. and not more than 22 per cent. by weight. Prepared pitch from tar distilleries must contain not less than 16 per cent. and not more than 28 per cent. by weight of free carbon; and commercial soft pitch not less than 18 per cent. and not more than 31 per cent. In the latter case the pitch may contain not more than 25 per cent. of pitch derived from tar produced in the manufacture of carburetted water gas—in place of the 10 per cent. given previously. The last-named alteration has also been made in the case of tar oils.

TUNNEL THROUGH APENNINES NEAR COMPLETION.

The tunnel being constructed through the Apennines at a cost of $30,000,000 is nearing completion. When the Croce di Monaco tunnel through the Eastern Apennines is finished, the last engineering difficulty in the way of finishing the Puglian aqueduct will have been removed. The aqueduct was begun in October, 1899, and will, it is hoped, be completed next autumn. By diverting the River Sele, which flows into the Tyrrhenian Sea below the Gulf of Naples, its waters are carried through the main range of the Apennines to the Adriatic coast of Italy and delivered to the three arid provinces of Puglia. The aqueduct begins at Caposele, 1,358 feet above sea level, and the main waterway running to the eastern slope of the mountains at Venosa is 132½ miles long, of which 60 miles are cut through the rocky mountains. At Venosa the supply is divided into three conduits, one branch running to Foggia, another to Bari and the third to Lecee, in the very heel of Italy. These three main conduits have a total length of 1,000 miles; while the distribution among the principal towns and communes has necessitated the laying [illegible]

It has been decided after exhaustive tests to use Pretoria cement in the extensive harbor works at Cape Town and Durban. The output of the Pretoria cement works is about 1,000,000 bags per annum, and the company hold contracts both with the government and municipalities. Great care is exercised in the manufacture of the cement and recent tests gave the following results in tensile strength, after seven days 786 pounds, and after 28 days 931 pounds. It is anticipated that the local cement will ere long entirely replace the imported article in South Africa.

DISCUSSION ON "PRESENT DAY WATER FILTRATION PRACTICE."*

By John H. Gregory,
Consulting Engineer and Sanitary Expert, New York City.

THE author has presented a paper which contains much of interest to waterworks engineers and superintendents interested in filtration, and there is much in the paper with which the speaker is in hearty accord. There are, however, some phases of the subject on which the speaker holds somewhat different views from those of the author, among which may be mentioned the questions of the cost and difficulty of securing sites for slow sand filters and those of the cost of both slow and rapid sand filters.

The author states: "It is true, on account of the much greater area required, the cost for land is far greater in the case of slow sand filtration systems than for rapid sand systems. Roughly, other things being equal, land will cost twenty times as much for a slow sand filter installation as for a rapid sand plant." There is but little question that, under ordinary conditions, the cost of land for slow sand filters will exceed that for rapid sand filters, owing to the larger area required, but that it will amount to as much as "twenty times" as that for slow sand filters is open to question. Those who have had experience in acquiring land for waterworks projects know that, even if only a small piece of land is required on which to locate the works, but that this piece of land is a portion of a much larger tract, the purchaser might often as well buy the whole tract of land as to buy only a small portion of it. Thus it may readily be that, in acquiring a site for rapid sand filters, much more land would be actually purchased than needed simply for the plant. It may be that the area required for the construction of a slow sand filter plant will be twenty times that required for a rapid sand filter plant, but that the land will cost twenty times as much does not necessarily follow.

In discussing further the question of site the author states: "Furthermore, in large projects, it is often difficult conveniently to locate a site for slow sand filters, while for a rapid sand filter plant it is a relatively easy matter as a rule. If it is necessary to go a long distance in locating an extensive and suitable area of land for a slow sand filter site there is incurred a large expense for a conduit to bring the filtered water to the city." The inference might be drawn from this that it has been exceedingly difficult to secure sites for large slow sand filter plants, but the history of many of the plants which have been built will hardly bear out this inference.

In commenting on some of the plants which the author mentions (*The Canadian Engineer*, April 30th, 1914, page 666), the speaker might say that he has been personally connected with seven out of the fifteen plants mentioned, and is familiar with the reasons which led to the selections of the sites on which these works were built. It is, of course, necessary to have land on which to build filters, whether of the slow or rapid sand type, but in the selection of a site local conditions are often a very important factor.

* Mr. Johnson's paper, presented at the recent Convention of the American Waterworks Association in Philadelphia, was published in abstract form in *The Canadian Engineer* for April 30th, 1914. Mr. Gregory presented the discussion, given herewith, at the Convention on May 13th.

At Albany, N.Y., for example, practically the first ground available on which filters of either type could be built and which could be purchased at a reasonable price, was that on which the slow sand filters were actually built, just north of the city line. It happened that there was another tract of land a little nearer to the existing waterworks pumping station, to which the filtered water was to be delivered, where it would have been possible to build either slow or rapid sand filters. To have acquired land there, however, for either type of filters, would have been very expensive. The site on which the filters were built had another advantage in that the intake there would be further away from local sources of pollution. At Albany the Hudson River is tidal. The sewage from the city was and still is discharged into the river without treatment and on flood tides there is often an upstream current which carries some sewage with it. It will be seen then that other factors than simply area of land alone may have a bearing.

At Pittsburgh, Pa., as far as the speaker is aware, no difficulty was found in securing a site for the slow sand filters there, which plant is one of the largest in the world. The filter plant is located directly across the Allegheny River from the Brilliant Pumping Station, from which most of the water used in the city is pumped. It is true that it was necessary to build conduits under the river to bring the filtered water to the pumping station, but the case would have been the same if rapid filters had been built instead, for, if the speaker's memory is correct, the best site on which filters of either type could have been built was that on which the slow sand filters were constructed.

For the four slow sand filter plants in Philadelphia mentioned by the author, namely, Torresdale, Upper Roxborough, Lower Roxborough and Belmont, and of which the writer had charge of the design, no trouble was experienced in securing suitable sites.

As regards the Lower and Upper Roxborough filter plants, local conditions were of the greatest importance in that it was necessary to utilize existing reservoirs as settling basins, as well as existing pumping stations and pipe lines. Somewhat similar conditions existed with reference to the Belmont plant, although in this case there was no reservoir which could be utilized as a settling basin.

The Torresdale slow sand filter plant is the largest single plant in the world, and if difficulty had been experienced in securing suitable sites for such works it would naturally be expected to have occurred here. Such was not the case, however, and the plant was built inside the city limits. It is true that the plant was located some distance upstream from the closely built-up part of the city, and that a conduit about 2½ miles in length was constructed through which filtered water is delivered to the Lardner's Point pumping station, but it was good judgment on the part of the city authorities to locate the works where they did.

The Delaware River at Philadelphia is tidal and is polluted by the discharge of sewage from the city, and it was to avoid pollution as well as to secure a site that the plant was built as far upstream as it was. It might be added further that the city has already constructed a small sewage disposal works just below the Torresdale filter plant, where sewage is treated and the effluent disinfected before discharge into the river, in order to guard against raw sewage from the nearest point from reaching the intake of the Torresdale filters. Had rapid sand instead of slow sand filters been built at Torresdale there is no question in the speaker's mind but that such a plant

would have been built as far upstream as were the slow sand filters.

One might fancy possibly that trouble would be experienced by the City of New York in securing sites for filters. Such is not the case. Over ten years ago the Commission on Additional Water Supply, in its investigations for an additional water supply for New York City, looked into the question of filter sites not only for the additional supply, but also for the Croton supply. Sites were found where slow sand filters could be built in close proximity to the existing Croton Aqueduct, and sites for slow sand filters were also found and surveyed where the additional supply could be filtered along the line of the proposed new aqueduct. Some years later the Department of Water Supply actually prepared detailed plans for a slow sand filter plant for the Croton supply, on a site located in New York City, namely, in the east basin of Jerome Park Reservoir, the construction of which was suspended pending a decision as to the filtering of the supply. In the case of New York City it is not a question of going a long distance and building an expensive conduit to get a filter site, but rather a question of going a long distance and building an expensive conduit to get water.

At Cincinnati, Ohio, the rapid sand filter plant, which is the largest of its kind in operation in the world, was built well upstream above the city where plenty of land was available for either rapid or slow sand filters. The filtered water is discharged through a long conduit to a main pumping station from which it is pumped to the reservoirs in Eden Park. This plant was built for the future as well as for the present, and it was good judgment to locate the plant as far upstream as it was.

At Columbus, Ohio, the rapid sand filters were built at some little distance upstream above the city. It was a case here of going upstream to get out of the flood zone, although sufficient land for either rapid or slow sand filters was available nearer the city. At the point where the plant was finally built there was sufficient land for either rapid or slow sand filters. In acquiring the land for this particular plant it was found that it would be about as cheap to acquire the whole tract of land on which the works were built as to acquire only so much of the same as would be needed for the plant alone.

Perhaps enough has been said to point out that factors other than the area of land alone have to be taken into account, not only for slow as well as for rapid sand filters, in selecting a suitable site.

The author also considers, in the table on page 69, the cost of construction of different types of filters. It is exceedingly difficult to compare satisfactorily the costs of construction of different plants, even where the fullest information regarding the same is available. Those who are not well posted as to the history of some of the plants cited in the table may possibly be misled as to the cost of building both slow and rapid sand filters if they accept the figures of the author without full knowledge of local conditions.

One of the features which very materially affects the cost of such works is the total reservoir capacity provided, that is the combined capacity of the settling basins and of the clear water reservoirs. To illustrate: The rapid sand filter plant at Little Falls, N.J., which, in the author's table is the most expensive one cited, and which cost $15,000 per million gallons daily capacity, has a coagulating basin capacity of 1.3 hours and a filtered water reservoir capacity of 2.6 hours, or 3.9 hours total reservoir capacity. At Columbus, Ohio, the rapid sand filter plant there, which the author states cost $13,000 per million gallons daily capacity, the next to the highest in cost cited, has a settling basin capacity of 12 hours and a filtered water reservoir capacity of 8 hours, making a total reservoir capacity of 20 hours, or five times as much reservoir capacity as that of the Little Falls plant. If the reservoir capacity of the Little Falls plant had been approximately that of the Columbus plant the cost of construction of the Little Falls plant would have been materially increased over that given by the author. Again, the New Orleans rapid sand filter plant might be cited, which has 35.2 hours' total reservoir capacity, or practically nine times as much reservoir capacity as that of the Little Falls plant. Other factors which affect the cost of construction are the character of the raw water, the rate of filtration, the character of the construction of the works, etc.

In his reference to the Albany slow sand filter plant, the author gives its capacity as 20,000,000 gallons daily. The Albany plant as originally built before the pre-filters were added, had a capacity of 15,000,000 gallons daily. The addition of the pre-filters increased the capacity of the plant very materially so that at the present time the capacity is probably in the neighborhood of 28,000,000 gallons daily. If the capacity is taken at 28,000,000 instead of 20,000,000 gallons daily the cost of the plant would be about $14,300 instead of $20,000 per million gallons daily capacity, as given by the author.

The Philadelphia slow sand filter plants were expensive plants to build. They differ in one way from many of the other filters of the same type that have been built, in that underneath the filter floors and carried up all around the sides of the filters is a layer of puddle. This item alone materially increased the cost of construction. The Lower Roxborough and Upper Roxborough plants were built on high ground in an isolated section several miles from the nearest railroad, and the cost of delivering materials to such plants was higher than would ordinarily be the case.

In the cost of the Lower Roxborough plant the author did not include the cost of the Lower Roxborough reservoir, which was built many years before, and which supplies settled water to the filter plant. Again, a similar condition exists at the Upper Roxborough filter plant with regard to the settling basin. The New Roxborough reservoir was built some ten years earlier than the filter plant, and the author has not included its cost in the cost of the filter plant. Strictly speaking, the costs of the reservoirs should be included in the costs of these two plants so that the figures would be comparable with the costs of the other slow sand filters cited.

The Philadelphia plants were built during a regime of very high prices, and to use the costs of construction of these plants to indicate the reasonable cost of slow sand filters may be very misleading, except to those who are familiar with the early history of these works and who are aware that the costs were high and that the plants could be duplicated at less cost.

The largest slow sand filter plant under construction in America at the present time is at Montreal, and, when completed next year, will have a capacity of 60,000,000 U.S. gallons daily capacity. The total cost of the plant, on the basis of the lump sum contract prices, including the low lift pumping station, will be about $22,600 per million gallons daily capacity. Deducing the low lift pumping station, the cost will probably be about $21,000 per million gallons daily capacity.

It would have been interesting if the author had cited the cost of the slow sand filter plant which was completed at Toronto about two years ago. This plant has

a capacity of 48,000,000 U.S. gallons daily, assuming one-sixth of the filter area to be held in reserve, and based on a rate of filtration of 6,000,000 U.S. gallons per acre daily, the rate for which the plant was designed. The cost of the plant, omitting the low lift pumping station, was only about $12,700 per million gallons daily capacity.

In considering the weighted average cost of slow sand filters given by the author, namely, $32,600 per million gallons daily capacity, it may be well to bear in mind that the Montreal plant will cost only about $21,000, that the Albany plant cost about $14,300 and the Toronto plant only $12,700 per million gallons daily capacity.

In referring to the cost of rapid sand filter plants the author cites the Columbus plant as costing $13,000 per million gallons daily capacity. This plant was designed and built under the writer's direction and is a water-softening as well as a rapid sand filter plant. The cost of this plant was given in great detail in a paper* read by the speaker some years ago. The speaker is not informed as to what items the author included in arriving at the cost of the Columbus plant, but in the speaker's judgment the Columbus plant, considered as a rapid sand filter plant alone, cost nearer $15,000 than $13,000 per million gallons daily capacity, the figure given by the author.

Another rapid sand filter plant which the author might have cited is that of Toledo, Ohio, the cost of which was published in the Engineering Record, November 26, 1910. Part of the plant was built for a capacity of 60,000,000 gallons daily, although the present capacity of the works is considerably less. Including only such items as are chargeable to the filter plant proper, the works cost about $14,500 per million gallons daily capacity.

Another rapid sand filter plant which might have been cited is that at Grand Rapids, Mich. The plant was completed inside of the last two years and has a capacity of 20,000,000 gallons daily. The cost of the plant, as given to the speaker by the Grand Rapids officials last year, including such items as are chargeable to the filter plant proper, was $16,300 per million gallons daily capacity.

In December, 1912, the City of New York received bids for a rapid sand filter plant to be located at Jerome Park reservoir and having a capacity of 320,000,000 gallons daily. The speaker is more or less familiar with the plans for the proposed Jerome Park filters as he served as one of a commission of engineers appointed by the Board of Estimate of New York City to report on the same. Taking the lowest bid received and adding to it the cost of the building and other necessary work, the Jerome Park filter plant, which would have been the largest rapid sand filter plant in the world, would have cost about $18,400 per million gallons daily capacity. When the plant is built, and it is greatly to be hoped it will be built soon, the actual cost will probably be in the neighborhood of $20,000 per million gallons daily capacity, as much of the excavation for the plant has already been completed.

The author gives the cost of the Cincinnati rapid sand filter plant, which has a daily capacity of 112,000,000 gallons, as $11,400 per million gallons daily capacity, and states that the cost of the large, plain sedimentation basins is not included. At Cincinnati there are two large settling basins to which the raw water from the Ohio River is pumped. The water is first settled in these two basins, and is then delivered to the coagulating basins at the filter plant. There is no question in the speaker's mind but that the settling basins are part of the filter plant at Cincinnati, but just how much of the cost of the same should be chargeable to the filter plant may be a question. Mr. J. W. Ellms, the superintendent in charge of the filters at Cincinnati, in a paper printed in the Journal of the Association of Engineering Societies in January, 1912, states:

"The settling reservoirs, which have a capacity of 330,000,000 gallons of available water, are in part a portion of the water purification plant, although they also serve the purpose of storage basins and were designed for such a use quite as much as they were for sedimentation purposes."

The two settling basins cost $1,521,000, or about $13,600 per million gallons daily capacity of filter plant. Adding this cost to that of the filter plant would give a total cost of $25,000 per million gallons daily capacity. As the settling basins serve as storage reservoirs also, it may be reasonable to charge the filter plant with perhaps only half their cost. On this assumption the cost of the settling reservoirs chargeable to the filter plant would be $6,800 per million gallons daily capacity, thus making the total cost of the filter plant $18,200 per million gallons daily capacity.

Still another plant which the author might have cited, and among the best in the country, is that at New Orleans, which has a capacity of 40,000,000 gallons daily. Including only such items as are chargeable to the filter plant proper, the cost of the New Orleans plant was about $30,200 per million gallons daily capacity.

The weighted average cost of the Columbus, Toledo, Grand Rapids, Cincinnati and New Orleans rapid sand filter plants, is $18,600 per million gallons daily capacity, while the author gives a weighted average cost for rapid sand filters as $12,100. In other words, the weighted average cost of the five plants just cited, all of which are in operation and which are among the best in the country, is over 50 per cent. higher than the weighted average cost given by the author.

The speaker has but little further to say on the subject of cost except that, in his judgment, the weighted average costs as given by the author, are too high for slow sand filters and are too low for rapid sand filters. Similarly the fixed charges on the costs of construction would respectively be too high for slow sand and too low for rapid sand filters.

The speaker is not presenting any brief for slow sand filters. The rapid sand filter is more flexible than the slow sand filter and in the majority of cases in the United States is better adapted to the purification of water than is the slow sand filter. The slow sand filter has done and is still doing good work in this country, and the present status of water purification is, to a large extent, due to the introduction of the slow sand filter.

*Trans. Am. Soc. C.E., Vol. LXVII., 1910.

The Board of Railway Commissioners has recently issued a general order respecting an application of one of the railway companies to cover Circular No. [illegible], dated May 5th, 1914, whereby the railways were required to submit monthly, in duplicate, reports on fires originating within 300 feet of the track and burning off an area of [illegible] square feet or more outside the right of way. The applicant petitioned that the circular be treated as privileged and not open to the inspection of the public generally. The Board complied with their request, ordering that such reports shall be made public or given out upon application, and, therefore, only by its own order.

BRIDGE OVER NORTH THOMPSON RIVER, BRITISH COLUMBIA.

A FEW months ago a deck girder bridge 1,209 ft. in length with a girder lift span 93 ft. long and a height of lift equal to 53 ft. was completed for the Canadian Northern Railway Company over the North Thompson River at Kamloops, B.C. Approaches of timber trestle construction at both ends of the bridge have a total length of 1,123 ft. The fixed spans, 12 in number, correspond in length to the lift span, giving the whole structure a very well proportioned and balanced appearance. The lift span is second from the centre span of the structure, as shown in Fig. 1.

Fig. 1.—General View of the Thompson River Bridge.

The lift span weighs 118 tons and is operated by the assistance of counter weights attached to cables engaged in sheaves at the top of the towers, as shown in Fig. 2. The ends of the span ascend in guides so designed as to make due allowance for elongation due to changes of temperature and for changes in live loan. Cables, 1¼ in. in diameter, at each corner of the span pass over drums and are actuated through a system of gears by a gasoline engine, which, together with all the equipment, is located below the deck and between the girders in the centre of the span.

Fig. 2.—View of Lift Span, Showing Elevating Mechanism.

Centering castings provide for keeping the span in proper alignment when being seated. These castings also look after the longitudinal braking thrust. The track is equipped with the necessary special castings at the ends of the span to give continuity to the rails and with locks at each end of the bridge. Limit switches, coming into operation as the span is approaching its bearing, or its elevated position, control the igniter circuit of the engine which, under ordinary operating conditions, is capable of raising the span 53 ft. in 100 seconds, thus providing a clearance of 55 ft. above high water.

The bridge was designed by Messrs. Waddell and Harrington, consulting engineers, Kansas City, Mo. Mr. H. L. Johnston, divisional engineer for the C.N.R., represented the railway in its construction.

The approximate cost of the bridge was $250,000.

CANADIAN ELECTRICAL ASSOCIATION.

The twenty-fourth annual convention of the Canadian Electrical Association will be held in Montreal June 24, 25, 26 and 27, with headquarters at the Ritz Carlton Hotel. Local committees have been appointed and consist of the following:

General Committee—Major Hutcheson and Mr. J. S. Norris, joint chairmen; Messrs. L. D. McFarlane, E. F. Sise, G. H. Olney, R. S. Kelsch, R. J. Jones, J. M. Robertson and Dr. L. Herdt.

Ways and Means Committee—Mr. Julian C. Smith, chairman; Messrs. K. B. Thornton, J. A. Shaw, R. H. Balfour, W. F. Graves and R. F. Morkill.

Entertainment Committee—Mr. Lawford Grant, chairman; Alderman Boyd, Messrs. Paul Sise, R. G. Harris, W. C. Lancaster, W. H. Winter, H. C. Post, P. Roper, Powell and R. M. Wilson.

Publicity Committee—Mr. S. W. Smith, chairman; Messrs. W. J. Doherty and L. J. Belnap.

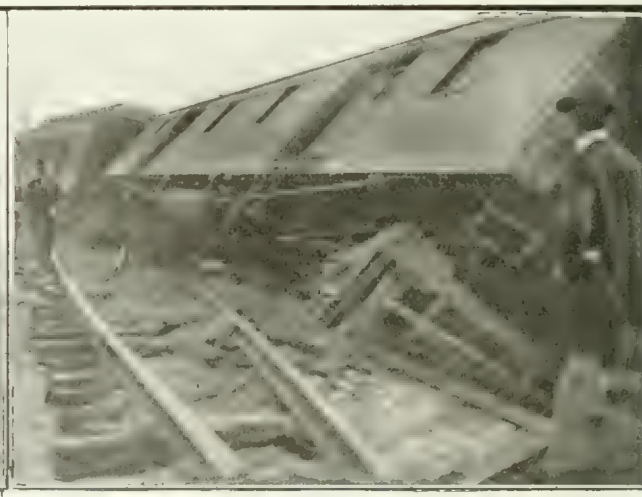
Finance Committee—Mr. J. W. Pilcher, chairman; C. F. Medbury, F. W. Smith, R. M. Wilson and L. B. Belnap.

P. T. Davies, honorary secretary.

A special programme has been prepared by the Entertainment Committee which is sure to appeal to all visitors. Special souvenirs have been provided for the ladies.

RECENT DERAILMENT NEAR TROUT CREEK, ONTARIO.

THE accompanying views give rise to some interesting conjectures in connection with train derailment. The accident which they illustrate occurred to the "Cobalt Special" at four-thirty in the morning. One of the Pullmans contained a party of railroad engineers, one of whom was looking out the window at the time, and it was stated positively that the speed at the moment of derailment did not exceed fifteen miles per hour. The extraordinary manner in which the rails, ties and ballast were torn out indicates the seriousness of such an accident occurring at this point at high or even moderate speed.



Views of Recent Derailment Near Trout Creek, Ont.

Apparently, one truck of one of the forward cars mounted the west rail, and after travelling along the ties for perhaps forty feet, commenced the process of tearing things loose. The following cars, on reaching the damaged roadbed, left the rails and completed the destruction. The point at which the rail was mounted was clearly indicated, though the gauge at this point and for some distance to the south was quite correct, and showed no reason for the derailment. When the train came to a stop, the tender and six out of the eight cars were off, some of which needed but little more to roll them completely over. One of the photos indicates three lengths of rail, detached from the ties and quite free from fish plates and bolts, apparently lying close to their original positions and not in any degree twisted or otherwise damaged.

We are indebted to Mr. K. L. Aitken, consulting engineer, Toronto, for the photos illustrating the mishap.

CONCRETE ARCH BRIDGES.

The following conclusions drawn in a paper, "Concrete Bridges; Some Important Features of Their Design," by Walter M. Smith, Sr., and Walter M. Smith, Jr., in Vol. 39, p. 1193, Proceedings of the American Society of Civil Engineers, are of interest. This paper deals with the advantages of an arch of two ribs over the solid soffit arch, with narrow ribs rather than wide ribs and with deep ribs of I-section rather than rectangular section; it also deals with the advantages of the three-hinged arch over the fixed and two-hinged types.

The writers believe that the following conclusions are amply justified by the investigations:

(1) An arch span consisting of two separate ribs is more economical than one with a solid soffit, if the span is greater than 100 ft.

(2) Narrow, deep ribs are more economical than thin, wide ones.

(3) The three-hinged arch is more economical and reliable than fixed or two-hinged arches for spans greater than 100 ft.

(4) For spans of 200 ft. or more the rib of I-section is more economical than the rectangular rib.

(5) Piers of any considerable height are much more economical if built of two separate legs thoroughly braced, thickening rapidly in the direction of the axis of the bridge as they go down.

On June 2 the steel mills of the American Steel and Tinplate Company, which have been idle for many weeks, were ordered into service again; and nine of the eleven mills began running. The other two are being repaired.

A plan is under way and is being furthered by the Baden government, Germany, to dredge and widen the Rhine River from Strassburg to Constanz; and the project is declared to be a perfectly feasible one. The dredging and widening of the river portion from Strassburg to Basle, would, it is considered, be an integral part of the main waterway from Strassburg to Constanz; and the Rhine should be made navigable to Constanz or not at all. For Baden, the undertaking is one of great importance as it would eventually open up a waterway for the largest steamers from the North Sea to the Baden Sea.

Coast to Coast

Woodstock, Ont.—Estimates for the year 1914, totalling $83,082.81, have been approved by the London city council.

Sarnia, Ont.—The Dominion Government has commenced dredging along the docks of the Northern Navigation Company at Point Edward.

Windsor, Ont.—Niagara power will be delivered in Windsor by August 1. All the towers are placed, and installing of equipment is progressing rapidly.

Hamilton, Ont.—Another offer has been made to the city of Hamilton of property to be purchased for a civic stone quarry. The firm of Teeter & Kemp offer 110 acres in the township of Saltfleet for $30,000.

Ottawa, Ont.—The city council of Ottawa has adopted a motion calling for the appointment of a committee to inquire into the existing organization regarding the construction and maintenance of roads, and to bring in a report.

Swift Current, Sask.—No further drilling will be done at the Swift Current gas well until October 1. Collarless pipe must be secured from Germany before the contractors can carry the depth of the drill to 3,000 feet, as recently decided upon by the city.

Oil Springs, Ont.—It is stated that the new Oil Springs oil and gas strike on the Wallen property is now estimated at a capacity of 12,000,000 feet per day, and this in consideration of the fact that drilling has only been carried a couple of inches into gas rock.

Weyburn, Sask.—A recent discovery was made a few miles south of Weyburn of an extensive quarry of what is claimed to be excellent sandstone. The deposit is located one mile from the C.P.R. station at Ralph, and shows a seam about 8 feet thick and 50 feet wide.

Toronto, Ont.—City Surveyor Le May has outlined a scheme for the remodelling of North Toronto, which is now being considered by civic authorities. The project calls for the extension of many streets and the opening of others, which will reach an expenditure of about $1,000,000.

Vancouver, B.C.—Paving work at Vancouver, recently contracted for by the Canadian Mineral Rubber Company, is progressing rapidly. Within a few weeks, a total yardage of approximately 16,000 square yards has been completed, and the company is now busy at the resurfacing of Vancouver street.

Winnipeg, Man.—Work is reported as showing satisfactory progress on the power plant of the Winnipeg Electric Railway Company being built at Grand Bonnet Falls. In April a private railway along the company's right-of-way was commenced, and is being rapidly built. It will extend 12 miles from Lac du Bonnet to the power site.

Sudbury, Ont.—The construction of the Sudbury-Copper Cliff Suburban Electric Railway has been commenced, and it is the intention of the company to have the line completed this year from Sudbury to Copper Cliff. Three lines are contemplated at present, e.g., Copper Cliff route, 5.1 miles; Ramsay Lake route, 1.2 miles; and Frood Mine route, 1.2 miles.

Toronto, Ont.—The works committee of Toronto has recommended to council submission of money by-laws amounting to $1,734,465, as follows: roadway section, asphalt plant, $125,000; sewer section, $121,400; Dundas street bridges, $148,000; North Toronto water supply mains, $525,000; extension of high-pressure system, $500,000; other mains, $315,000.

Vancouver, B.C.—City officials of Vancouver observed recently tests of pressure made at the First Narrows on the water main recently connected between the north and south shores, which have been reported as very satisfactory. It is stated, also, that the work of hauling across the second 18-inch main, which is to form one of the connections for the Point Grey partnership pipe line, will commence at once.

Ottawa, Ont.—The compromise reached in connection with the question of the liability of the government in guaranteeing the bonds necessary to complete the construction of the G.T.P. mountain line, provides that the government shall guarantee bonds for three-quarters of the additional cost required for completion. It is understood that the amount of the guarantees, including interest, is $16,000,000.

Edmonton, Alta.—It is claimed by experts who have spent years north of Edmonton that oil fields will be developed to the north of the province which will prove to be of much greater moment than those in south-western Alberta now attracting world-wide attention. The country is said, by geologists, to show both surface and geological indications of the greatest oil development.

Ottawa, Ont.—The city auditor of Ottawa has reported to the city council that the total cost so far of the work on the old intake pipe is $153,849.37, as given in a statement prepared by the city engineer's office. Of that amount, already there has been passed $122,708.45, of which $82,636.63 has been for extras. The city engineer's estimate for the entire work was only $57,000, and the contract was let to Loomis, McBean and Williams for $40,000.

Victoria, B.C.—An inspection was made recently by D. O. Lewis, divisional superintendent of the C.N.P. railroad, particular attention being made to Section D, which lies between mileage 100 and 140. The grade from mileage 124 to 135, which runs through heavy rock work, has been practically completed. It is said that this section of the road is in splendid condition, requiring but little more attention at the hands of the contractors. Nothing has been done, of course, between mileage 136 and 140, where there are alternative routes between which a choice has yet to be made.

London, Ont.—Actual construction work undertaken this year by the city engineer's department under by-laws passed by the council now totals $525,000, a small amount of this having been authorized last year. The road work being carried out in the city is well under way. The concrete work on Horton street from Ridout street bridge has been completed, and the work of laying vitrified brick surface can now be undertaken. Work on the Wharncliffe road sewer has been commenced and will be completed, it is expected, within two weeks; after which the laying of pavements will proceed.

Victoria, B.C.—The laying of concrete flow line along the route between Humpback reservoir and Cooper's Cove in connection with the Sooke Lake water supply works, is reported to commence shortly. Enough pipe is ready to proceed with work on this section as well as on the line from Sooke Lake to Cooper's Cove, where work is in progress. Also for the section of the pressure line between the reservoir and the city, the fabricating of steel pipe will soon be commenced by the Burrard Engineering Company. Preparations are being made for procedure on excavation for the line, continuing on from the point where excavation now stops.

Fort William, Ont.—Owing to the fact that, upon breaking through many of the pavements in Fort William, it is found that the earth has sunken below them, leaving no support whatever, a new system of street paving is being advanced by M. Ferguson and J. H. Walker, of west Fort William. Their plan is to construct a line of concrete piers under the crown of a pavement and to run a reinforced con-

crete beam over the top of these as a support to the pavement. If, as in the case of some of the city roads, the sewer is laid in the centre of the street, they propose that two rows of piers be constructed, one row on each side of the sewer. With such a system, it is said, the pavement would carry the greatest loads even when the supporting earth sinks away beneath it.

Brandon, Man.—In an address made to the Brandon Trades and Labor council upon the power question, Mayor Hughes advocates as the most feasible and profitable way of getting power for Brandon the hydro-electric scheme from the Winnipeg river. In support of his contention, Mr. Hughes gave the following figures for the cost of power from Winnipeg: cost of line from Portage to Brandon, $297,903, this to include transformers, patrol and upkeep of the line, $5,500 per annum; one-half cost of line from Portage to Winnipeg, $12,630; 2,500 h.p. at $20, $50,000, making a total of $91,386 for power and upkeep of line. Speaking of the probable income, the speaker said that from the waterworks $20,000 would be realized; from the street railway, $12,000; and from the street lighting, $18,000. These sums were in addition to revenue from two flour mills, the C.P.R., C.N.R., and numerous smaller plants.

Vancouver, B.C.—A recent report on the construction of C.P.R. bridges over the Pitt and Harrison rivers in British Columbia says that structural operations are now well advanced on the double-track bridge being erected by the C.P.R. over the Pitt River. The huge swing span, 276 feet in length, and weighing 650 tons, is being erected; and girders are being placed from the eastern end of the structure. Nearly one-third of the upper portion of the bridge has been erected; and the work is expected to be completed in November. The structure is 1,750 feet in length, and will be the largest of its kind on the British Columbia division of the C.P.R. Also rapid progress is being made on the Harrison River bridge, a structure of a similar type to the Pitt River bridge, and 950 feet long. The superstructure is nearing completion, the swing span having been installed and work well advanced from both ends. It will be ready for service, it is anticipated, by the end of July.

Brantford, Ont.—The Board of Water Commissioners has awarded contracts for a new waterworks pumping plant. Two De Laval 12-inch, multi-stage, centrifugal pumps, two De Laval single-stage, double suction type booster pumps, and two high-speed turbines for driving the booster pumps, will be supplied by the Turbine Equipment Company, Toronto. The contract for the 250 h.p. synchronous motors for driving the domestic pumps has been awarded to the Canadian Westinghouse Company, Hamilton. The output of each of the domestic units will be 4,000,000 imperial gallons per day, against 200 feet head. The output of each of the booster units will be 4,000,000 gallons, against 100 feet head. In case of the electrical power being out of commission, the two booster pumps can be arranged to run in series, the output being 4,000,000 gallons against approximately 90 pounds pressure. In case of fire, either booster pump can run in series with either electrically-driven domestic pump.

Ottawa, Ont.—The city council of Ottawa has passed the first reading of by-laws authorizing the issue of debentures totalling about $1,000,000, which include the following amounts for local improvements: $44,239.33 for sewers; $164,846.84 for asphalt pavements; $10,206.23 for opening of Murray street; $14,385.41 for opening of Heney street; $93,530.53 for asphalt pavements; $14,008 for tarvia pavements; $98,571.91 for concrete sidewalks; $159.50 for plank sidewalks. Other items of expenditure are: $5,000 to complete main drain system; $5,000 to pay city's share of cost of subway on Bank street; $8,000 to pay for cost of alterations and additions to Howick hall; $50,000 for construction of horticultural and agricultural hall; $30,000 for completion of main drainage system along certain streets; $25,000 for trunk sewer in Rideau ward; $80,000 for bridge over canal; $60,000 for cost of intercepting sewer through Broad street yard of C.P.R.; $40,000 for new hydrants and water meters; $80,000 for water mains and extensions.

Sault Ste. Marie, Ont.—According to a judgment made public at Ottawa on June 4 by the International Joint Commission in the case of the Michigan Northern Power Company and the Algoma Steel Corporation, these companies are to be allowed to divert 30,000 cubic feet of water per second from the river; and this means the development by Sault Ste. Marie of 106,000 continuous electrical h.p. The capital cost of the development will be $13,250,000. Throughout the consideration of the case the paramount rights of navigation interests have been kept in mind; and the powers given the companies are contingent upon the construction of a dyke so operated under Government supervision as to ensure the maintenance of the level of Lake Superior. Under the lease by the United States Government to the Michigan Power Company the dyke and sluice-gates on the American side will eventually be acquired by the United States Government, and similar action will probably be taken by the Canadian Government in respect to the works on its side of the river.

Toronto, Ont.—The plans for the Don section of the Bloor Street viaduct, as designed by Engineers Thomas Taylor and C. W. Power, of the Civic Works Department, show a straight stretch of construction from Castle Frank road east to the present western terminus of Danforth avenue, with a high bridge of 4-arch span crossing the Don Valley and river, the longest span to be 282 feet from pier to pier. The deck of the viaduct is divided longitudinally into three sections, the two outward sections being devised for street traffic, the central section for rail. A ballasted roadbed is planned to deaden the noise customary in connection with traffic bridges. Moreover, provision is made in the plans for providing a lower deck to the viaduct in future to accomodate rapid transit railways; and whenever the growth of street traffic warrants, it will be possible with little alteration and expense to remove all the cars from the upper deck and to provide a clear roadway from one side of the viaduct to the other. Preparation of plans for the Rosedale section of the viaduct are almost completed. This section comprises two diagonal stretches from Sherbourne and Bloor Street south-east to the head of Parliament Street produced, and thence north-east to Castle Frank road.

Vancouver, B.C.—Besides the Central Park section of the trunk sewer to be constructed by the Greater Vancouver joint sewerage commission, and for which tenders are to be advertised shortly, there are many other portions of work, some of which are also included in the 1914 program outlined by the commission. Sections which are in a fair way to being realized are the Clark drive interceptor, which will take all the sewage from China Creek to Burrard Inlet; extensions to the present Bridge street sewer, the construction of that along Balaclava street, and the laying of a trunk line east of Hastings Park, extending from the inlet some distance south of Hastings street; the Stanley Park interceptor, which will do away with the outfall at English Bay and will carry all sewage from the West End into the First narrows; and the deepening of the Brunette river, which will lower Burnaby lake and allow of better drainage of the surface water in the section of Burnaby municipality in this vicinity. The China Creek trunk sewer and its tributary, the Canoe Creek extension, are now in progress; and the city is preparing to lay lateral sewers draining into the trunks, which will serve D.L. 301, hitherto without sewers of any kind. Up to the present, at least $200,000 has been expended on the work.

OIL ENGINES FOR FISHERIES.

The attention of Canadian manufacturers of oil engines suitable for fishing craft, is drawn to the increasing demand in Great Britain, by the report of Mr. J. E. Ray, Canadian trade commissioner at Birmingham. There seems to be a very keen competition in the supplying of oil engines for this purpose as all types of British fishing boats are being equipped with motors as auxiliary power. The leading British manufacturers of heavy type paraffin and hot-bulb engines are said to be extremely busy. A well-known firm in England secured in one week recently fourteen orders for paraffin motors of 55 and 75 b.h.p. to be installed in boats on the coast of Scotland.

The outfitting of these boats with motor power has had a remarkable growth during the last few years. Nearly all the new intermediate boats and yawls on the east coast of England have motors. Fishing craft, large and small, along the Irish coast and at the Isle of Man ports are also being fitted. The same applies to the south of England, to the Shetlands and to the west of Scotland. Scarcely a new boat is being turned out in which a motor is not installed.

PERSONALS.

WM. FORBES has been appointed road superintendent for the County of Oxford, Ont.

A. M. JACKSON, of Brantford, has recently been appointed engineer to the County of Brant.

GEO. B. TAYLOR was recently appointed superintendent of the power and water departments of the city of Medicine Hat, Alta.

E. R. SMITHRIM, B.A.Sc., has been engaged by the Public Utilities Commission of Strathroy, Ont., to superintend the construction of its distribution system for Hydro-electric power.

C. G. DAVEY, a 3rd year student in mechanical engineering at the University of Toronto, has been awarded the scholarship of the Boiler Inspection and Insurance Company of Canada.

CHAS. W. POWER, assistant engineer, City of Toronto, in charge of the Department of Railways and Bridges has resigned and on July 1st, will become associated with the Canadian Stewart Company, Toronto, as engineer in charge of harbor work.

CARL WEBER, the inventor of the Weber reinforced concrete chimney, has become president of the Gun-Crete Company of Chicago. The firm specializes in cement-gun work for engineering, mining and industrial structures, and is also introducing the Weber system of hollow concrete floor construction. These floors are erected without forms and are said to be sound, fire and water proof and of light construction.

At the University of Toronto commencement exercises held on June 5th, the professional degree of civil engineer of the University of Toronto was conferred upon Messrs. P. Gillespie, associate professor of applied mechanics; C. R. Young, assistant professor in structural engineering; T. H. Hogg, assistant hydraulic engineer, Ontario Hydro-Electric Power Commission, and S. N. Hill, Topographical Surveys Branch, Department of the Interior, Ottawa.

The degree of electrical engineer was conferred upon R. A. Sara, sales manager, Winnipeg Light and Power Department.

OBITUARY.

On June 1st, Mr. Chas, C. Nugent, of Toronto, was fatally injured in a motorcycle accident. Mr. Nugent was 35 years of age and a native of Ireland. Since his arrival in Canada seven years ago he has been engaged in civil engineering work, during which time he has been connected with the Toronto staff of the Canadian Pacific Railway.

The death was announced on June 2nd, of Mr. Wm. R. Perrin of Chicago, architect, engineer and contractor for the Toronto civic abattoir. Mr. Perrin was 54 years of age and was head of the firm of W. R. Perrin and Company, Chicago and Toronto.

In the list of those who met death in the disaster which befell the Empress of Ireland is included the name of Mr. A. E. Barlow whose activities in mining and geological work throughout the Dominion are widely known. Mr. Barlow was for many years connected with the Geological Survey of Canada. During another period of his career he held a professorship in McGill University, Montreal. For some years prior to his death he has been engaged in private practice as consulting engineer and geologist. Only recently Mr. Barlow made some extensive investigations in British Columbia in connection with which he took passage to England on the ill-fated liner.

On June 5th death came accidentally to Mr. Rob't. H. Jupp, engineer for Simcoe County, Ont. Mr. Jupp was inspecting the construction of a bridge at Nicolston when he fell a considerable distance as a result of a misstep.

COMING MEETINGS.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30th to July 4th, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—Summer convention to be held at Brighton Beach, N.Y., July 3rd and 4th, 1914. Secretary, J. R. Wemlinger, 11 Broadway, New York.

UNION OF CANADIAN MUNICIPALITIES.—Annual Convention to be held in Sherbrooke, Que., August 3rd, 4th and 5th, 1914. Hon. Secretary, W. D. Lighthall, Westmount, Que. Assistant-Secretary, G. S. Wilson, 402 Coristine Building, Montreal.

AMERICAN PEAT SOCIETY.—Eight Annual Meeting will be held in Duluth, Minn., on August 20th, 21st and 22nd, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

CANADIAN FORESTRY ASSOCIATION.—Annual Convention to be held in Halifax, N.S., September 1st to 4th, 1914. Secretary, James Lawler, Journal Building, Ottawa.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chausse, 5 Beaver Hall Square, Montreal.

CONVENTION OF THE AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—To be held in Boston, Mass., on October 6th, 7th, 8th and 9th, 1914. C. C. Brown, Indianapolis, Ind., Secretary.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9th to 13th, 1914. I. S. Pennybacker, Executive Secretary, and Chas. P. Light, Business Manager, Colorado Building, Washington, D.C.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21885—May 27—Approving location C.N.R. proposed third-class station at Marvin, Saskatchewan.

21886—May 27—Approving location C.N.O.R. station grounds at Clemow, Tp. Barron, Dist. Nipissing, Ont., mileage 133.26 from Ottawa.

21887—May 20—Rescinding Order No. 21217, dated Jan. 16th, 1914. And directing that Can. Nor. Que. Ry. fence portion of its right-of-way between mileage 26 and 27, on south side of track, on or before June 1st, 1914.

21888—May 26—Authorizing, temporarily, pending installation of interlocking plant to be called at crossing, Toronto and Eastern Ry. Co., to operate trains over crossing of G.T.R. Port Perry Branch at Town of Whitby, Ont., for construction purposes only; interlocking plant to be installed on or before July 20th, 1914. All movements of Applicant's trains be flagged over crossing by an employee of Applicant Company.

21889—May 27—Dismissing complaint of Mrs. Kate S. Massiah, Lachute, Que., alleging discrimination by C.P.R. against Lachute, in issuing commutation tickets to St. Agathe, Vaudreuil, Hudson, and other points.

21890—May 27—Authorizing C.P.R. to construct road diversion in S. W. ¼ Sec. 3-8-29, W. 2 M., Sask., and construct, by grade crossing, its Weyburn-Stirling Branch Line across said road allowance between S. W. ¼ Sec. 3 and S. E. ¼ Sec. 4-8-29, W. 2 M., mileage 105.23, on said Branch Line.

General Order No. 125—May 30—Directing that terms of Judgment, which is hereby made part of this Order, and tariff changes therein directed to be made, be complied with and become effective not later than Sept 1st, 1914; and that, for period of two years from date of this Order, no rates at present in effect west of Port Arthur, Ont., be increased without approval of Board.

21891—May 27—Authorizing C.P.R. to construct siding for I. L. Lafleur, town of Notre Dame de Grace, from point on southerly limit of right-of-way of main line, Eastern Div., mileage 2.54, Windsor Street, to Montreal Jct., in Lot Cadastral Nos. 181-23, 24 and 25, (Civic) Notre Dame de Grace Ward, city of Montreal, Mun. of Parish of Montreal, Co. Hochelaga, Que.

21892—May 27—Authorizing C.N.R. to construct across and divert highway between Secs. 15 and 16-11-22, W. 2 M., at Traux, Sask.

21893—May 26—Authorizing C.N.O.R. to construct, by means of a separation of grades, across G.T. and C.P.R. Cos., in city of Toronto, Ont.

21894—May 27—Amending Order No. 21508, dated March 14th, 1914, to allow G.T.P. Ry. to make certain changes in highway crossings in Tp. 34, Rgs. 1 and 2, W. 3 M., Sask.; and extending for period of 30 days from 31st May, 1914, time within which said work required under Order No. 21508 was to be completed.

21895—May 27—Authorizing G.T.P. Ry. to construct spur for Inland Lumber and Building Co., Ltd., Edmonton, Dist. North Alta., Alberta.

21896—May 26—Authorizing G.T.P. Ry. to construct highway crossing over its main line in N.W. ¼ Sec. 7-53-4, W. 5 M., mileage 44.9, Sunset Ave., Whitewood Sands, Alta.

21897—May 27—Authorizing G.T.R. to construct siding and spurs therefrom, into premises of Elias Rogers Co., Limited, leased from G.T.R., city of Toronto, Ont.

21898—May 27—Authorizing G.T.R. to construct siding into premises of United Drug Co., Limited, city of Toronto, Ontario.

21899—May [illegible]—Authorizing G.T.R. to use and occupy branch line authorized to be constructed by T., H. & B. Ry. to lands of National Steel Car Co., Limited, under Order No. 17562, with full right and power to run trains over and upon said spur, subject to any Orders or directions Board may hereafter make as to exercise, enjoyment, or restrictions of powers and privileges herein granted, and subject to and upon certain conditions.

21900—May 27—Directing that Dominion Atlantic Ry. employ flagman to protect crossing of highway west of Port William Station, N.S., when trains are passing Port William Station without stopping.

21901—May 28—Amending Order No. 21243, dated Jan. 21st, 1914, by striking out word and figures "Fifty ($50.00)" in last line of Order and substituting therefor "Ten ($10.00)."

21902—May 29—Approving agreement entered into between Bell Telephone Co. and Byron Telephone Co., and dated May 14th, 1914.

21903—May 29—Approving agreement entered into between Bell Telephone Co. and Alnwick Rural Telephone Co., Limited, dated May 15th, 1914.

21904—May 29—Directing C.P.R. construct subway under tracks crossing highway between lots 5 and 6, Con. 5, Tp. Toronto, Ont., proposed subway be constructed in line with highway so there will be clear view through it from highway at each end; headway, 14 ft.; clear span of 20 ft. over crown of highway. Cost of construction, 20 per cent., not exceeding $5,000, by railway. Grade-Crossing Fund, 5 per cent., remainder by village of Streetsville, 15 per cent. Tp. Toronto, and 80 per cent. by Ry. Co. Surface of road be maintained by Municipal authorities responsible for highway; all other cost of maintenance be borne and paid by Railway Company.

21905—May 28—Dismissing application Town Aylmer, Que., for reduction in fare between Ottawa and Aylmer on Hull Electric Railway.

21906—May 29—Refusing application St. Mary's Horse Shoe Quarry, St. Mary's, Ont., for Order relieving it from expense of maintenance and interest charged upon G.T.R. spur into their property.

21907—May 28—Directing Lake Erie and Northern Ry., at own expense, to construct level crossing over railway where it crosses farm of Bradford Bowlby in Lot 5, Con. 2, Tp. Woodhouse, Ontario.

General Order No. 126—May 28—Declaring that report or reports submitted by Railway Companies in accordance with Circular No. 133, are privileged, and shall only be made public or given out upon application therefor by Order of the Board.

21908—June 1—Amending Order No. 21837, May 18th, 1914, by adding after figures "589" in 3rd line of recital to Order words and figures, "and No. 1186, certified copies," and striking out words "a certified copy"; and striking out word "condition" and word "Order" in 1st and 2nd lines of operative part of Order and substituting word "conditions" and word "Orders."

21909—June 1—Extending, until August 15th, 1914, time within which G.T.R. complete work of lighting Victoria Bridge, Montreal.

21910—June 1—Relieving G.T.R. from providing further protection at crossing of railway immediately west of Lorne Park Station, Ontario.

21911—June 1—Amending Order No. 21725, April 29th, 1914, by striking out following words and figures: "the said crossing to be constructed in accordance with Standard Regulations of Board Affecting Highway Crossings as amended May 4th, 1910," in last three lines of operative part of Order.

21912—May 27—Authorizing C.P.R. to construct diversion of Graham Ave., town of Stonewall, Man.; authorizing Co. to construct, by grade crossing, its main line, Man. Div. Arborg Sub. Div. across Lilly St., said town of Stonewall.

A weekly paper for engineers and engineering-contractors

THE MODERN METHOD OF SEWER VENTILATION

OUTLINE OF ESSENTIAL FEATURES OF THE MOST POPULAR SYSTEM—IMPORTANT CONSIDERATIONS TO GOVERN STORM AND DRY WEATHER FLOW.

By DR. ERWIN KOHLMANN, Dr.-Ing.; Dipl.-Ing.

THE modern method of sewer ventilation consists of numerous openings to the sewers from the atmosphere. This system has met with great success in Germany and in the United States of America, as it promotes an ample circulation of fresh air in the sewers.

This system is the direct opposite of that in which the circulation of air or the ventilation is promoted by using, artificially, individual factors as motive powers for the process, as it favors the co-operation of all the factors which have any influence on ventilation by a continual motion in all parts of the sewerage system through numerous openings, and the resulting continuous circulation of air tends to restrict the formation of obnoxious gases.

If the sewerage system is properly designed and constructed with grades sufficient to ensure a self-cleansing velocity, the sewage will always be in a fresh condition, and thus the generation of gases would be reduced to a minimum, for in spite of the best designed systems there will be, to a certain extent, a small deposit of sewage adhering to the walls of the sewers caused by the constant fluctuation of the flow and with it the generation of gas, but by proper ventilation this danger is overcome, as the oxygen contained in the atmosphere destroys all substances adhering to the walls or otherwise deposited in the sewers by oxidation, thus by the strong dilution of the sewer air with the fresh air the nuisances caused by sewer gases are avoided.

This system of ventilation consists of the installation of two groups of connections between the sewer and the atmosphere, the one at the lowest possible point (such as the openings in manhole covers) and the other at the highest possible point (such as the rain water and soil pipes on houses). The differences in the levels of inlet (the lowest point) and outlet (the highest point) form the main movement of the current of air.

First we will consider the high level group. If the down pipes are connected directly to the sewer, that is without any trap, there would be created a series of highly located connections with the atmosphere, which, in combination with the manhole orifices, would present favorable conditions for the forming of such a considerable difference in levels. To produce an upward current in the down pipes, it is necessary to have a source of heat so that the air in these pipes would exceed the temperature of the atmosphere. In cold weather the source of heat is promoted from heated buildings, and a very small excess of temperature is necessary to promote a velocity sufficient to influence the process of ventilation. Even in winter the co-operation of these down pipes can be relied on for the circulation. In summer the conditions are much more favorable, as are also those times during the action of the sun's rays.

This system of ventilation is much more efficient in streets which are located east and west, and the efficiency extends annually to 2216.2 hours or 25% of the year.

In times of storm, the upward current is eliminated. This condition has often been cited against the use of down pipes for the purpose of the ventilation of public sewers, but when it is considered that the rain duration is only 518 hours annually, or 6% of the total, and the sewers during rain are cleansed by the indraught of air, there is no reason why this should be considered seriously, especially when we consider that this system requires no artificial assistance and, therefore, no expense. However, in residential districts, or in houses where the attics are used for dwelling purposes, it is not advisable to use the down pipes for the purposes of ventilation, so that only the soil pipes could be used.

The pipes most suited for ventilation are those in proximity to the furnace or kitchen chimneys, as the surroundings during the whole of the year have a heat exceeding that of the sewer air, and correctly, soil pipes have been termed the "natural chimneys of ventilation."

The temperature always being higher in the soil pipes causes the motion of the air, and if these pipes were extended to a height above the roof, either of the same or larger diameter, they would form a perfect means of maintaining the continuous current of air from the manhole inlets through the sewers into the atmosphere, and even in times of storm their efficiency is not impaired if a protecting cowl is provided to prevent the admission of rain or air attracted by rain. (Fig. 1.) In draughty locations, the efficiency of these pipes as a means of ventilation may be increased by providing a revolving cowl, but if this is provided, provision must also be made to protect the house traps from their seal being broken, which is done by secondary ventilating pipes. Experiments were made in Cologne by Dr. Unna* with the revolving cowl without protection to the house traps, when it was found that the seal was broken.

In reference to the irregularity of the direction of the current, this is governed by local conditions. Frequently there are special conduits for sinks and bath waste which also partake in the process of ventilation. If these are

*Gesundheits-Ing., 1898, 21 Jahrg., No. 4 and No. 5.

located some distance away from any source of heat or on exterior walls, as is found in conveniences which are placed in a shed or outhouse, a downward motion takes place by which the efficiency is lessened and the ventilating influence on the sewer is reduced considerably. Since the efficiency of house drains is greatest if all pipes are placed in a warm location, provision should be made in local by-laws compelling owners of houses to continue the soil pipe to a sufficient height above the roof, and in the case of new buildings the soil pipes should be placed as close as possible to a chimney. In this manner the irregularity caused by the house drains in cold locations would be overcome, and more house connections would co-operate in the removal of the sewer air. The greater the suction, and the more house connections there are, the better would be the condition of the sewer air.

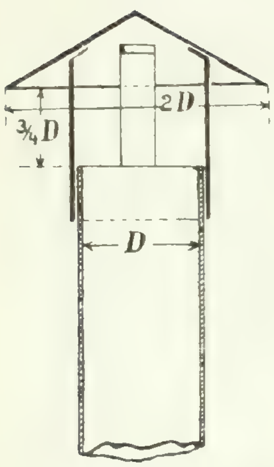

Fig. 1.—Cowl for Soil Pipe.

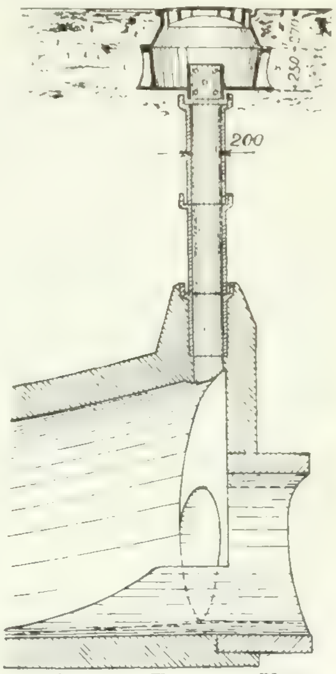

Fig. 2.—Type of Vent Shaft.

It might be mentioned here, that occasionally a downward current of air is caused by waste water from sinks and baths, but this discharge is generally of such short duration that the matter is not worth considering. On the other hand, if the question is raised against the downward current, it should always be borne in mind that a reversion of direction helps to flush the house drains thoroughly, and owing to the large number of remaining house drains it does not interfere with the general process of ventilation and is, therefore, desirable. If the ventilating efficiency of the soil pipes is irregular, the reason can generally be found in the absence of, or defective, air inlet.

We will now consider the second group, viz., the connections between the sewer and the atmosphere at the street level. These air inlets consist principally of perforated manhole covers. The distance separating these covers should range, in small sewers, from ninety to one hundred and fifty feet, and in large sewers from one hundred and eighty feet to three hundred and thirty feet. If the distances are greater than this, the addition of a special shaft would be necessary.

Under normal conditions, in dry weather, a continuous circulation from the manholes through the sewer to the houses takes place and the constant current will only be occasionally interrupted, as stated above. In times of storm, these conditions would be different. On a shower of rain entering a sewer an energetic air current is caused, which has a reverse direction to that during dry weather. A large volume of air is attracted through the down pipes by the accelerated falling velocity of the rain, and is conveyed into the sewers. The mixture of air and water fills the sewer, causing air tension.

Since the house connections, in time of rain, are soon submerged, the air cannot escape from the sewer through these drains, it will, therefore, try to find its way through the sewer to the street gullies. It cannot escape through these gullies owing to the quantity of surface water discharging from them. If the seal in the trap of the gulley is sufficient to resist the air pressure the escape of sewer air is prevented, and thus the only exit would be through the perforated manhole covers. If these covers are not perforated the air cannot escape and the sewers will become air-bound, so that the gullies will not be able to discharge into them, thus causing the streets to become flooded, and the pressure of air in the sewer would still be increasing until the manhole covers are forced and the joints of the sewer blown, causing considerable damage.*

In spite of the provision of perforated manhole covers flooding may still occur unless care is taken to have a sufficient number of manholes and their covers provided with an adequate number of perforations such that they will not be ventilating covers in name only. Many proposals have been previously made on account of the former unreliability to use only the perforated manhole covers or only the house connections for the ventilation of the sewers, but all these have been rejected. No group *per se* could be both inlet and outlet. On the other hand, heavy showers displace the sewer air by completely filling the cross-sections of the sewers, thus promoting circulation as well as in dry weather the differences in levels and temperature. We would not abstract from considering showers as favorable for the ventilation, but it would be better to improve the existing defects so that all trouble which may occur during storms will be avoided. An installation often resorted to is the provision of vent shafts similar to those shown in Figs. 2 and 3. Although these vent pipes are most essential during periods of rain, they also materially assist the circulation during dry weather.

These vent shafts serve two purposes, viz., to assist the manhole inlets when these are a considerable distance apart and to act as outlets for sewer air during heavy rains, when the house connections to the sewer are submerged. Thus, the installation of these vent shafts is recommended as an auxiliary means to promote thorough ventilation.

Since the connections of the sewer with the atmosphere at street level have serious disadvantages in some cases such as the danger to traffic caused by the holes in the manhole covers, the difficulty of cleaning and keeping the holes in the cover open, which is of vital importance for circulation, attempts have been made to substitute the perforated manhole covers by providing air inlets from the sidewalks or by the gullies.

The first method, that of inlets from the sidewalks, would scarcely answer the purpose, apart from the initial cost, as the maintenance would be a prohibitive expense, if adequate circulation is to be constantly maintained, on

*[NOTE.—An illustration of such an occurrence was reported in the Toronto daily press following a severe rainstorm on June 7th last. The pressure became so great in the Garrison Creek sewer that a section 20 feet in length was blown out; flooding Willowvale Park, it is announced, to a depth of 3 feet, with water and sewage.—Editor.]

account of the amount of silt and dirt collected in the pits. Another reason is the complication of the construction of these inlets which is not adaptable to the simplicity which should always be attempted to attain in ventilation and sewerage systems.

The second method is that of using the gullies. The theory is advanced that there are a greater number of gullies on a street than there are manholes, and the perforations of the manhole covers are not nearly the area of the openings in the gulley grating, and that these perforations, if not properly made, are liable to become clogged. This method has its advantages, as in dry weather there would be a greater number of air inlets, but it is questionable whether the gulley as a vent outlet in times of heavy rain accomplishes its purpose. The opinion of the author is that larger quantities of air are attracted by the discharge of the gullies rather than allowing the

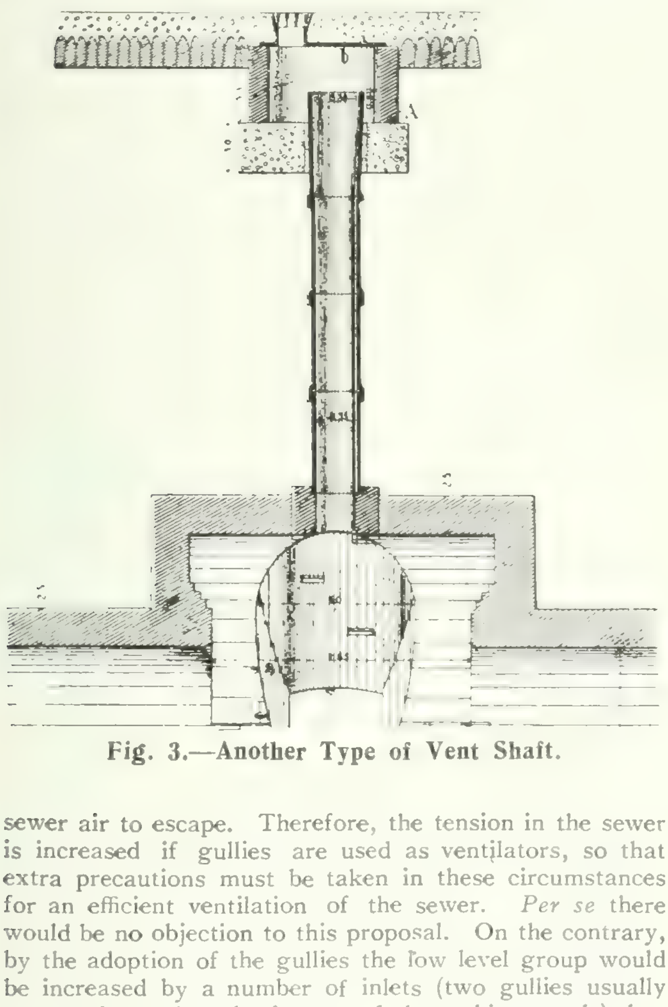

Fig. 3.—Another Type of Vent Shaft.

sewer air to escape. Therefore, the tension in the sewer is increased if gullies are used as ventilators, so that extra precautions must be taken in these circumstances for an efficient ventilation of the sewer. *Per se* there would be no objection to this proposal. On the contrary, by the adoption of the gullies the low level group would be increased by a number of inlets (two gullies usually arranged on a length of street of about thirty yards) thus presenting a double number of low level connections by which, in dry weather, a better circulation would result. It is doubtful, however, if the gulley as a vent outlet during times of storms accomplishes its purpose owing to the house connections being submerged. In the opinion of the author, large air quantities are rather attracted by the discharge of the gullies and the tension of the sewer air is, therefore, increased. If the gullies are used as ventilators, special precautions must be taken for an efficient ventilation of the sewers in these times. This takes us back to the adoption of perforated manhole covers, where in times of rain the displaced sewer air will collect, and by which during the dry weather the renewal, even of the upper air strata, is best obtained.

As already mentioned, the connection of the sewer with the atmosphere at the street level has two disadvantages, the ascending of sewer air during heavy rains, and the danger of the holes in manhole covers to the horses. An emanation of sewer air, however, in a well-ventilated sewer takes place only if the same is filling rapidly. Objection to by-passers cannot occur by this, as a well-ventilated, well-flushed, and above all a properly designed and constructed sewer contains only fresh and no decomposed sewage, and thus no foul air.

It is of absolute importance that the orifices in the manholes should be made small enough to reduce the danger caused by the horses catching the studs of their shoes in the holes. It is a mistake to replace covers with large openings by covers with small ones, as is sometimes done, which are even then ineffective as they become clogged by silt. The author is of the opinion that the manhole covers are the cheapest and most suitable means for low level ventilating orifices, and these openings can be brought into practical form by due consideration. By the suitable selection of orifices in arrangement and construction, accidents would be decreased, but to eliminate them would be practically impossible even with the most approved style of covers. According to an investigation conducted by Herrn Falkenroth with the covers of various designs, he proves that the danger to horses is decreased by the use of large openings and the proper construction of the ventilating orifices. The requirements of an ample air circulation in dry weather and unhindered removal during storms are fulfilled likewise by large openings, which are not so liable to become clogged.

The long segmental, oblong, square, radiated orifices cannot be considered, due to the danger to horses. After Falkenroth's experiments, the manhole covers with circular openings proved to be the most satisfactory. The openings in all cases should be inverted conical so that stones and silt could then fall to the receiving tray placed under the cover, and the selection of sufficiently wide circular orifices (1½-in. or more) will also exclude, or at least restrict to a minimum, the number of cases of traffic troubles or accidents. Simultaneously with the correct choice the requirements of an ample circulation will be fulfilled. Cities that have replaced the former covers with covers having circular openings have succeeded by this innovation, and the openings have met the requirements in reference to favorable circulation, safety to traffic and cleanliness. (See Fig. 4.)

Whilst the most suitable form of ventilation known may be adopted, it cannot be said that the sewer ventilation problem has been solved. In spite of the circular openings it may be necessary to consider the possibility of occasional sewer tension during storms. The great draught in the upward direction retards the adequate air escape. The quick run-off of the sewage requires the installation of sufficient and uniformly distributed openings for the expulsion of the air. Since sewer ventilators are fewer than house drains, comparatively, the ventilating conditions would be much more favorable if a means was found in another group of low level connections to assist the ventilating orifices of the manhole covers during time of storms. This assistance may be obtained by the cooperation of street gullies. The gullies are at present generally constructed in such a manner that the silt washed away by precipitation is retained in special receptacles, and the gullies are trapped from the sewer. This construction has two great disadvantages, viz., the nuisance of foul odors and the danger of silting up. The receptacles of the street gullies, and to a certain extent the house gullies, on hot days and days of atmospherical

fluctuations form a source of malignant odors. The deposits washed off by precipitation, consisting principally of paper, rags, street sweepings, fallen leaves, etc., mostly of an organic nature, undergo decomposition during their retention, often lasting for months, and thus pollute the air in the streets. A still more serious danger is caused by the traps. The light matter passing the gulley grating is not naturally retained, but frequently chokes the trap. Catch pits and water traps should be rejected in any case, even if cleaning takes place frequently. Firstly, the removal of the collected silt is neither

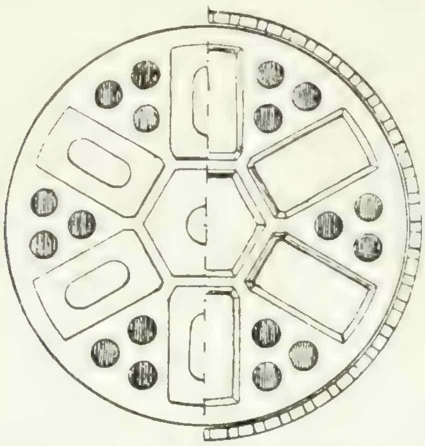

Fig. 4.—Manhole Cover With Circular Perforators (by Falkenroth).

hygienic nor æsthetic, and secondly, the silt retained in the receptacles will decompose and eventually infect the freshly entering flow, which will reach the sewer in a strongly contaminated state. With proper ventilation and flushing arrangements, however, in a sewer with sufficient grade, it would not lead to odorous nuisances, thus there is no necessity for a trap.

Simplicity should be the standard of a sewerage system, also the protection against odors of any kind. Therefore, the catch pits and traps should be discarded. It should always be the endeavor to prevent obstacles in design so as to remove the sewage, in fresh condition, as quickly as possible without any objection to the senses of sight and smell, from any dwellings. For this reason the water trap between the sewer and house drains has been rejected as unsuitable and the catch pits in the manholes abolished, as both have been the cause of a direct offence to inhabitants. Why is this measure not extended to the catch basins of the gullies and down-pipes? Why pin our faith to catch basins and traps in gullies, while close beside them manholes are built without catch pits, and their covers are, without any objection, equipped with ventilating perforations? The contradiction to this condition should be the best argument for the abolition of catch pits and traps. As soon as the catch pits are omitted no silt will be retained which would cause nuisances, and when the traps have been abolished there will be no more choking of gullies. Above all, an exceedingly favorable opportunity for a constant ventilation would be acquired. Indeed, in recent times prominent sanitary engineers were always advancing the advisability of the correct recognition of these advantages for the abolition of the gullies in the present form. Indeed, in recent times prominent sanitary engineers were always advancing the advisability of the correct recognition of these advantages for the abolition of the gullies in the present form. Prof. Ewald Genzmer advanced this desirability in the sewerage of the city of Schwetz (Fig. 5) which was designed by the author, and so did Stadtbaurat Fleck at Dresden. On the other hand, it will always be those who doubt the economy of such an enterprise who will speak against the generalization of the measure adopted in Schwetz. Such views can be discarded if we consider the figures. Generally one meets with the view that the quantity of silt retained by the catch pit would result, if omitted, in considerable additional cost for the cleaning of sewers. A calculation made by the author based on the annual report and the budget of the city of Dresden may lead to this aim.

According to the annual administration report of this city for 1911, the gullies in paved and macadam roads were cleaned in the recorded time, four times a year, in asphalt and wood-paved roads, sixteen times, on account of the bigger amount of silt conveyed into the gullies of the latter by precipitation and the more frequent washing. The catch basins of the down-pipes were cleaned only once a year.

The street gullies contained, on an average, 1/25 to 1/30 cu. yd. of silt, while that from the house gullies was only .07 to 0.11 cu. ft. The total silt removed was 4154.21 cu. yd. and the cost amounted to $5,250.

Frequently the washing of a street suffices to fill the gulley completely, so the catch basin or the tray in the basin will not be able to contain the larger quantity of silt which is washed away at times of precipitation. The silt, moreover, passes directly into the sewer where it is carried away by the sewage flow, or by flushing. The cost for the removal of street silt is, to the greatest extent, generally included in the cost for the cleaning of sewers, and only the smaller part comes into consideration for the cleaning of the gullies.

On investigation as to whether the sewers are able to withdraw the silt retained in the gullies or whether by its artificial removal by means of flushing, additional cost would ensue. Figuring on a water consumption of

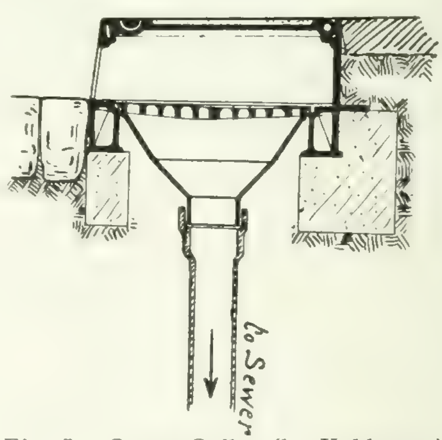

Fig. 5.—Street Gulley (by Kohlmann).

$120 l = 4.24$ cu. ft. per capita per day, it would mean for a population of 550,000 3,139,200 cu. yd. sewage per annum. The annual quantity to be removed from the gullies, however, only amounts to 4154.21 cu. yd. or 1.32 per M. of the D.W.F. (dry weather flow). Considering, further, a solubility of silt matter of 36%, the silt quantity would be able to be reduced to .085 per M. of the D.W.F. This small amount would doubtless be removed without any extra cost for haulage expenses by the uniformly flowing current of the D.W.F.

The conditions during times of storm are quite different. It is generally believed that the increased velocity, and larger flow in the sewers would have a greater clear-

ing capacity. This is not the case. By practice it is shown that during a storm the greatest deposits will occur in the sewer. It was found by the author that the rainstorm of July 10th, 1912, deposited in a trunk sewer on the Terrassenufer at Dresden, a quantity of grit of 52.32 cu. yd., while under normal conditions the weekly flushing operation removes only 2.6 to 5.2 cu. yd. of grit in the same sewer.

Since through the lower parts of the sewerage system, in consequence of abolition of the catch pits, large quantities of silt will pass, there is a danger that in times of storm a greater deposit of silt will take place. The reason is that in times of storm only the suspended matter is attracted, which is taken into eddies, the remaining silt is deposited especially where the velocities vary considerably. The additional cost which the cleaning of the sewers involves would by no means be so great as that required for the cleaning of gullies. According to Herrn Kajet, the cost of cleaning gullies amounts to 30% to 40% of the total cost of cleaning sewers.

There is another reason for the abolition of the catch basins. It has often been stated that it is more rational to remove the silt from the gullies instead of the sewers, as they are more accessable. However, if it is considered that the periodical removal of quantities of silt from the gullies (in some cases weeks elapse before they are cleaned) can be executed only with difficulty and with a certain amount of nuisance, a method would be preferable by which the removal of street sweepings is obtained hygienically and æsthetically unobjectionable condition which is inevitable in the most perfect design of cleansing implements. This advantage offers the odorless and invisible removal of the street sweepings by the sewers. By this method a further advantage is obtained, viz., that the quantity of silt containing organic and mineral matter which is soluble up to 64% on its way, according to the time in which it remains in the sewer, is considerably reduced until eventually in the grit chamber at the sewage disposal plant a complete separation of the organic matter is affected, that is, the separation of the sludge proper from the mineral constituents, the heavier suspended matter. If the cross-section of the grit chamber is designed in such a manner that the velocity is never less than one foot per second, so the grit will settle while the putrescible sludge passes into the settling tanks with the fresh sewage without being affected whatsoever.

As the removal of the detritus in the grit chamber is effected principally by machinery, the result is of further economic advantages to this system, indeed a disposal plant will have, by the collection of the soluble and suspended constituents of the street sweepings, an overcharge, but the cost for cleaning would not be materially increased as the amount of soluble and suspended matter is only 36%, and but .085 per M. of the dry weather flow. Applying this to the Dresden conditions means that in the most favorable case, instead of 4154.12 cu. yd. of street sweepings which are carried into the sewer, only 2659.16 cu. yd. of mineral matter will settle in the detritus chamber. The cost of removal of 1 cu. yd. of silt amounts, in the Dresden-Neustadt plant, to about 38 cents, including the wages of men and maintenance of the dredge, while the cost for cleaning the gullies amounts to $1.34 per cu. yd. This example may suffice to dispose of the objections of those who have doubt in the economy of the method to convey the street sweepings directly into the sewers.

If, however, in some special cases, such as mountainous districts or asphalt and macadam roads, larger collections of sand are carried off by the quantities precipitated, and find access into the gullies it may be advisable to arrange small catch basins. In cases of paved roads, however, the arrangement of catch pits must be designated as absolutely obsolete. Together with the catch pits, there would obviate the last installations which would cause the pollution of the air, and thus the air of public sewers and of all connecting pipes to these would lose their offensive odor and character. With the abolition of traps indeed we have gained a further series of low level connections which effect at least as much as the perforated manhole covers and the co-operation of which for the ventilating process, in reference to the overweight of the domestic soil and down-pipes compared with the vent openings at street level restricted by the limited number of manholes, is of an importance which should not be underestimated. Indeed, we had to make certain alterations in construction in order to use the gullies for continuous ventilation.

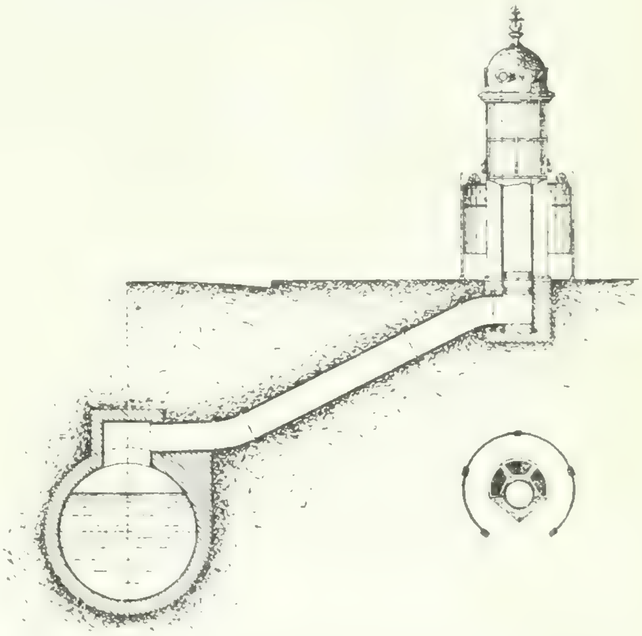

Fig. 6.—Ventilating Device on a Paris Trunk Sewer.

Gullies are generally adopted with cast iron gratings, either parallel or rectangular to the curb line. One may be of different opinion as to the advantage or disadvantage of both kinds. While it has been observed that in some cities gratings with bars parallel to the curb permit a better passage for floating matter, such as pieces of wood, paper, leaves, etc., other cities prefer, for the same reason, gratings with rectangular bars. With regard to the safety of traffic, both designs are not approved. On one side it is stated that horses with their studded shoes have been caught in gratings of the second style and damage resulted therefrom, while the opponents maintain the same gratings of the first design. In both cases the cause is probably to be found in the unsuitable construction of the gratings, too narrow slits, or their unfavorable location in the gutter. In any case, a well-designed grating has proved itself to be a rain inlet in flat streets. With the correct location in the gutter, gratings with sufficiently wide openings and rounded-off corners, which prevent the catching of studded shoes of horses, will fulfil all requirements in regard to safety both of run-off and to traffic.

Regarding the ventilation, it is more difficult to obtain sufficient results with this construction. With gratings, the experience has been found that in times of storm the large quantities of rain running off and extending over

the grating, in consequence of the collected floating matter, does not permit the air trapped in the gulley to escape. To overcome this difficulty, the area of the grating should be increased by which the desired results can be obtained. The process performed thus is that the upper part of the grating collects the water and the lower will allow the escape of sewer air. An increase in the grating cannot always be obtained, especially in narrow business streets or steep roads, where the horses are equipped with heavy shoes and long studs; alternations in the design of these gratings have to be made. In steep roads where gratings do not answer the purpose, on

Fig. 7.—Superstructure for Ventilating a Trunk Sewer in Dresden. (The dome is equipped with self-recording rain gauges.)

account of the high velocity of the surface water and especially if the surface water contains much floating matter, it runs over the grating and the expensive and difficult installations of pre-grates have to be adopted so as to prevent the flooding of the streets in the lower districts. In these hilly districts gullies with side entrances have been successfully adopted. The side inlet gulley comprises all the advantages to the safety of run-off and of traffic, as well as ventilation. It carries away all floating matter and particles liable to clog the ordinary grating, and at the same time there is no danger to horses. With this installation the circulation of air in the sewerage system will always remain normal, as in times of storm its inlet is never wholly covered, thus the escape of air is not hampered. For these reasons the side inlet gulley is preferable and the adoption of gratings should only be permitted temporarily as is done in Schwetz, where broad streets with very little traffic are equipped with gratings.

It frequently happens that larger foreign-matters are placed malignantly into the side entrance gullies by which the choking of the inlet takes place, which would otherwise be kept clear by the increased clearing power of the water rushing down. The removal of these matters can only be performed with difficulty and at considerable expense. The author considers it advisable to provide a funnel-shaped inlet with a movable grate, the openings of which are so arranged that only such matter is retained by which a choking of the drain is liable. By this method the ventilation would not be impaired.

By omitting the traps in the gullies the advantage is secured of the prevention of tension in the sewer air which is produced by the air adhering to the water in times of heavy precipitation. Even if the surface water discharged by the gullies contains atmospheric air, the ventilating orifices in the manhole covers will be relieved. As in times of storm, large quantities of air enter the sewer, attempts have been made to separate the mixture of air and water by what is known as air separators contained in bends or orifices in the down-pipes or special vent pipes in the down-pipes, but these attempts should not be considered on account of the dangers which may arise by the interruption of the duties required by the down-pipes.

Probably a better means for the conveyance of the air attracted through the down-pipes is by the use of the domestic soil pipes. It is a general practice in a combined system to convey the storm and sanitary flow by a common conduit to the sewer. Thus there would be no reason, in a combined sewerage system, to construct the house drainage on the separate system. With regard to the ventilation, however, there would be objections, and a separate introduction of storm and soil pipes from domestic premises into the sewers would be desired as well as in combined systems. We have already recognized the soil-pipes as the material means for sewer ventilation during dry weather as they are able to maintain by their higher temperature a constant current of air in the direction from the sewer to the atmosphere. It does not seem advisable to exclude these uniformly acting factors from the ventilating process during times of storm and to connect them with pipes which do not act air-ejecting as those do, but air-forcing. By the accelerated falling velocity, the down-pipes convey, during times of storm, quantities of air and water with such intensity that it cannot be of any effect to the soil-pipes on the sewer. If it is further considered that in dry weather the connection of both pipe systems in a common conduit promotes independent currents by the difference in the temperature prevailing between the down-pipes and soil-pipes, which results always in a trouble of the aspiring efficiency of the house connections on the sewer. The author thinks it advisable to introduce down- and soil-pipes as separate conduits. This would show that during dry weather the influence of the soil-pipe on the removal of the sewer air is greater than by the separation of the down-pipes and the trouble in the operation on the ventilating process would thus be eliminated.

During times of storm the sewers are quickly filled so that the house connections, the mouth of which are placed just above the level of the dry weather flow in the sewers, are soon submerged. It might be proposed to effect the introduction of the house drains at the top of the sewer. Thus, the ventilation of the sewerage system by means of the soil pipes would in any case separate again the quantities of air introduced by the down-pipes, and no tension in the sewer would occur.

If the introduction of the house drains at the dry weather flow level was placed so as not to be offensive to the workmen in the sewer by the discharge of domestic sewage, there would be no objection to the carrying out of this proposition for the inaccessible sewers, and as the exceedingly greater number of conduits in each sewerage system consists of inaccessible sewers there would be maintained in this greater part of the system an ample

circulation and during times of storm the air quantities introduced by the roof water would easily be removed. With this construction no special auxiliary means, such as vent shafts, would be required. In larger sewers this proposal can scarcely be effected. Here also, a possibly high introduction of house drains would be desired. A higher location of the mouth in height of the springing line could not be attained as already in normal conditions in larger sewers complaints of offences become numerous

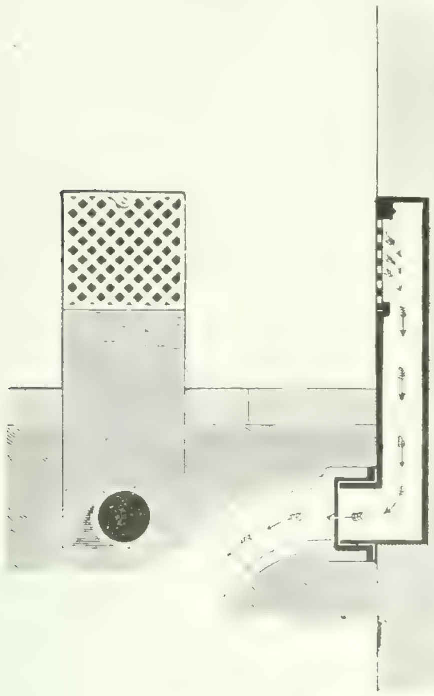

Fig. 8.—Air Inlets.

by the workmen in consequence of the splashing of sewage. Thus in big sewers where the distance between the manholes is greater, the adoption of vent shafts must be introduced.

Every sewerage system has further series of subterranean structures not to be avoided, such as side entrances or shafts with stairs. At these points the air would reach, under circumstances, abnormal tensions. On the other hand, these chambers will flood during times of storm and will be covered with sludge so that in such cases sufficient ventilation should be provided. These should be located at the highest points, as a nuisance to passers-by and neighbors may arise. They should also be equipped with special vent pipes which lead to suitable places in the atmosphere. In Paris, for instance, this is done by the use of the numerous public urinals, and in Dresden special superstructures have been erected over special entrances. (Figs. 6 and 7.) In some cities the efficiency of these vent pipes has been increased by artificial means, and in Brunswick gas stoves were used until recently in the trunk sewer vents. Leipzig used two electric fans to increase the suction through the vents, while in Magdeburg the aspiring ability of houses and high chimneys for the removal of the sewer air has been effective, similar to the ventilating efficiency of the soil pipes. In low-lying districts where manhole covers are air-tight, generally on account of floodings which occur, other means of ventilation must be adopted. In order to effect the circulation by two groups at different levels, a number of inlets have to be installed in lieu of air-tight manhole covers which could be designed in such a manner as is used in England. (Fig. 8.) The removal of the sewer air will then be performed by the soil pipes, or if this is insufficient an additional number of special vent pipes have to be provided.

The question as to the most efficient system of the ventilation of public sewers can therefore be answered thus: By constantly keeping a circulation of air in the sewers during the time of dry weather flow, thus preventing development of gases, and at time of storm to eliminate air tension. Therefore, there must be a constant circulation during dry weather from the perforated manhole and street gullies, without a trap, through the sewer to the soil pipes placed in a warm location and carried above the roof, and in times of rain an air current must be possible in the reverse direction from the down pipes to the manholes. The gullies without a trap and the soil pipes have to perform the separation of the attracted atmospheric air.

In such a manner it would be possible to remove the sewage from houses and premises without creating a nuisance or source of danger to the health of the community by the sewer air, and thus the modern system, that of numerous openings to the air, will have reached the highest degree of perfection.

DRAINING OF KERR LAKE.

An interesting feature of 1913 mining development operations in the Cobalt district was the draining of Kerr Lake in order to make available the ore in the immediate lake bottom, and also to allow prospecting under the lake to be carried on with greater safety. The following notes on these draining operations at Kerr Lake during the summer and autumn of 1913 have been supplied by Mr. Robert Livermore, manager of the Kerr Lake Mine, and appear in the recent report of the Temiskaming and Northern Ontario Railway, prepared by Mr. Arthur A. Cole, Mining Engineer to the Commission:—

After the granting of permission in May, by the Mining Commissioner to dewater Kerr Lake, work was taken in hand at once. All preliminary surveys had been made some time previously, defining the route for the water via a 20-in. pipe line directly from Kerr to Giroux Lake, crossing the Kerr Lake property over the height of land between the two lakes. The greatest elevation of the line above water level of Kerr Lake is 53 feet, the linear distance from lake to lake 2,400 feet, and the difference in elevation between the two lakes 20 feet.

Kerr Lake at this time covered an area of 30 acres, of which 18 belonged to the Crown Reserve, 6 to Kerr Lake, and 6 to the former Drummond Mine. The purchase of the latter acreage by the Crown Reserve and Kerr Lake Companies jointly included the total area of Kerr Lake under the ownership of the latter companies, by whom the entire operation was jointly undertaken and managed. Soundings made of Kerr Lake during the previous winter had established the fact that there were approximately 400,000,000 gallons of water and semi-liquid mud. Giroux Lake covers some 230 acres, and is of great depth, with a large outlet flowing to the Montreal River, so that by using the direct route instead of via Kerr Lake outlet and Glen Lake, to Giroux as at first proposed, there was no possibility of flooding other properties.

On account of the necessity of pumping a certain amount of mud together with the water in order to clear the bottom of the lake sufficiently for mining purposes, and on account of the changing level of Kerr Lake, and the consequent increase of head against which this material must be pumped, a pumping plant capable of

great flexibility, not only in the nature of the material to be handled, and efficiency against a varying head, but also in changeability of base, had to be designed. This plant as finally installed consisted of four single-stage centrifugal pumps, arranged in two units. Each unit made a compound pumping outfit of two pumps, arranged one on each end of the base, with a direct-coupled motor between the two. The pump shells were 1½ in. thick, with removable side discs, the runners being of the enclosed type, capable of handling solids up to 4 in. in diameter. Each unit was designed to deliver not less than 3,000 gal. per min. at the highest elevation to be encountered. At the start the four pumps were to work in parallel, each discharging its own stream into the main pipe through specially cast fittings. When the head became so great that the best efficiency was not to be had, a change could be made from parallel to tandem operation simply by connecting the discharge from one pump of each unit to the intake of the other, by which arrangement two units, each of a two-stage tandem pump, could be obtained. The pumps were built by the Morris Machine Works, of Baldwinsville, New York. Their total weight is 28,000 lbs. The motors to run the pumps were furnished by the Canadian Allis-Chalmers Company. They are 250 h.p. induction motors, 2,200 volts, 3-phase, 60 cycles, having a synchronous speed of 1,200 revolutions per minute.

The pumps were mounted on a scow built at the Crown Reserve shops on the shore of Kerr Lake, of western fir throughout. 6-in. x 6-in. frame timbers, and 3-in. plank for sides, deck, and bottom were used. After installing the pumps and motors the scow was housed with a weather-tight superstructure.

Power was obtained from the line of the Northern Ontario Light and Power Company, which passes through the property.

Flexibility of connection was obtained between the pumps and the shore end of the pipe by 20-in. flexible ball and expansion joints, joined by a connecting flanged length of 20-in. pipe. As the level of the lake lowered new lengths of pipe were inserted between the ball joints, and supported by trestle bents, having slings for lowering the pipe as the level changed. The ball joint on shore was firmly bolted to a cement pier, and when the scow's distance from shore became too great for practicable support of the connecting lengths of pipe, the ball joint was moved down to the new water line, and re-established on a new pier. The scow was moored with wire hawsers at each corner passing to shore. These hawsers were manipulated by small capstans set up on shore and on the deck of the scow. In addition, two 30-ft. 14-in. x 10-in. spuds were provided, running in wooden guides at the stern of the scow, which could be raised and lowered at will, but in practice it was found that the mooring lines were ample to hold the scow in position.

The 20-in. pipe line connecting the two lakes was of the spiral, riveted, bolted, joint type, supplied by the American Spiral Pipe Works. This pipe was laid on the ground where possible, but where inequalities of the country made it necessary, on simple bents, two to each length. When the pipe crossed the township highway it was laid in a culvert blasted from the rock, and where it crossed the track of T. and N.O. Railway it was carried over, at a distance of 23 ft. above the rail, by two four-post towers, built of 8-in. x 8-in. timbers, somewhat of the ordinary aerial tram type. The angle of crossing made a span of 90 ft., for which three flanged lengths were used, supported by strap hangers at 8-ft. intervals, hooking over four ⅞-in. cables, passing over the tops of the towers in pairs, and anchored by logs set 6 ft. under a stone fill. The pipe line was carried directly to the water level of Giroux Lake, and later was extended in a long curve by extra lengths of pipe, and by a flume, to a remote cove of the lake, in order to avoid muddying the main body of the water.

As the two operating companies, and the Cobalt Comet Mine, formerly obtained their water for mine and domestic purposes from Kerr Lake, a new supply was necessary to take its place. To this end a permanent pumping plant was installed on the shore of Giroux Lake. A well 10 ft. square and 12 ft. deep was sunk in solid rock at the water's edge, and a 5-ft. cut blasted through to the lake. Over this well a pump-house was erected, and two single-stage turbine pumps, each of a capacity of 500 imperial gallons per minute against a head of 175 ft., driven by direct-connected motors, were installed. The speed of operations of these pumps is 1,750 revolutions per minute. The motors are each 45 h.p., 2,200 volts, 3-phase, and 60 cycles. The water-carrying line for this supply is of 8-in. spiral, riveted, bolted, joint pipe, 1,300 ft. in length, connected with a 46-000-gallon receiving tank, erected on the highest point of land between the two properties. From this tank the supply for the different mines is piped.

By the arrangement of the pump intakes in the well above described, the difficulty of protecting the suction lines against freezing, and of building secure piers, which would have been met with had the lines been carried out into the lake, were obviated. The various distributing pipe lines were securely protected against freezing by water-tight wooden boxes filled with sawdust, and heated by a 1-in. line carrying steam from the boilers.

A signal system, in which a float in the receiving tank, by making various electrical contacts at different stages of water, lit warning lights and sounded an alarm bell at the pump-house, was put in, and was found to work successfully.

The draining pumps were started on August 28th, and operations proceeded steadily until the cold weather in the latter part of November caused suspension of work, until this spring. The clear water was taken out very rapidly, and during the last three weeks of last fall's operations the pumps were handling mud alone. In all, some 325,000,000 gal. of mud and water were removed at an average rate of 6,000 gal. per min. for 38 actual working days.

Although the lake was not totally de-watered last season, a sufficiently large area was cleared to make available for stoping and development the most important blocks of ground of the two companies, and it was demonstrated that the remaining fluid could be pumped without undue difficulty.

Several important veins were disclosed, some of which had not been known before. One of the encouraging features revealed by the exposure of the lake bed was the fact that the top parts of the veins had been little affected through oxidation of leaching by the lake waters.

Allowing for the usual delays in delivery of equipment, and for a few changes of minor importance in the working out of the scheme, the installation was expeditious, and the operation successful from the standpoint of the two companies concerned. The novelty of the undertaking consisted not so much in the mere project of pumping out the lake, as in the working out of the numerous details, to which careful attention was necessary owing to the wide difference in the nature of material to be handled by the pumps, acting from a moving base against an ever-increasing head, and in these respects the problems involved seem to have been satisfactorily solved.

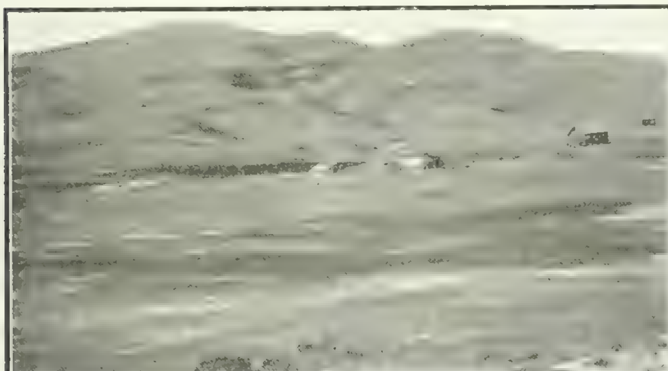
PROGRESS OF INVESTIGATION OF CLAY RESOURCES.*

By J. Keele,
Geological Survey of Canada.

During the season of 1913, the writer and two other members of the staff of the Geological Survey were engaged in examining clay deposits in various parts of the Dominion. The western provinces received the most attention, as they are dependent to a much larger extent on clay products for structural materials than the east.

The testing of clays and shales is one of the most important parts of this investigation, and occupies considerable time in the laboratory. An outline of the results of the field and laboratory work is as follows.—

Manitoba.—An examination was made of the shale deposits which are interbedded with the dolomitic limestones at the quarries in Stony Mountain and Stonewall.



White Fire Clay Beds in Dirt Hills, Saskatchewan.

Shale and Sand-stone Beds on Eastern Edge of Porcupine Hills, Southern Alberta.

White Clay in Edmonton Formation, Near Alix, Alberta.

Although these shales are hard and gritty, they become fairly plastic when finally ground and mixed with water, and capable of being moulded in clay-working machinery. Their lime content, however, is so high that they burn to a porous chalky body at all temperatures up to Cone 3 (1,190° C.). They could not compete with the surface clays of the district, which require no grinding and burn to a dense body at lower temperatures.

Samples of dark grey shales from Mafeking, sent to the laboratory for testing, were probably taken from the Benton division of the Cretaceous, which outcrops in this locality. These shales contained so much carbonaceous matter, as to be practically useless for the manufacture of clay wares. The carbon burns out of these shales with a bright flame, when they become heated to about 500° C., behaving in this respect like oil shales.

A plant for the manufacture of clay products is under construction at Carmen, this point being selected on account of the distributing facilities it offers for the manufactured wares. It is proposed to use the Niobrara shales from the Pembian Mountains near Leary, on the Carmen-Hartney branch of the Canadian Northern Railway. A carload of this shale was brought to Toronto during the winter and tested on a commercial scale in a sewer-pipe plant. The working and drying qualities of this shale were good, and a fairly satisfactory product with a bright salt glaze was turned out of the kiln.

Owing to the carbonaceous matter, and gypsum which this shale contains, the burning of wares made from it will be attended by some difficulty, until they are overcome by experience.

A mixture of the Niobrara and Pierre shales, both of which will occur abundantly in the Pembina mountains, will be found to give better results for sewer pipe.*

A consignment of clay samples from Sprague were tested in the laboratory. These, on testing, were found to be very similar to the surface clays at Winnipeg. They consist of an upper buff burning brick clay and a lower red burning clay. It is impossible to use the lower clay on account of its defective working qualities, but the upper clay makes an excellent common building brick.

Saskatchewan.—An examination was made of the clay deposits in the vicinity of the city of Saskatoon, and several samples were collected for testing. The results of the tests were not encouraging, as the materials present certain difficulties for successful working, and when these are overcome only the common grades of clay wares can be made from them.

Clay deposits at the town of Kamsack were investigated, the materials available at this point being buff burning surface clay overlying Niobrara shales of the Cretaceous formation.

The surface clays will make good building brick if burned sufficiently hard, but there is a tendency toward underburning and the consequent production of soft, porous wares.

The Niobrara shale in this vicinity is unworkable by wet moulded processes, owing to its excessive shrinkage and cracking in drying. This shale might be used for

*Published by permission of R. W. Brock, Deputy Minister, Department of Mines.

*Clay and Shale Deposits of the Western Provinces, Part II., page 93.

red dry-pressed bricks if the losses through fire checking did not run too high.

There is an extensive shale deposit almost precisely similar to this at Swift Current, an examination of which proved it to be subject to the same objections.

The Laramie formation in southern Saskatchewan contains clays which are the most valuable in the province.

The most important materials of this formation are the white or light grey, often sandy fire clays, and other deposits of a similar nature, but containing impurities which, for want of a better name, are called semi-refractory clays.

The fire clays of this region have fusing points between Cone 27 (1,670° C.) and Cone 32 (1,750° C.), while the latter fail in the fire test at Cone 15 (1,430° C.) to Cone 25 (1,630° C.).

Certain deposits of these types have already been described in published reports,* but their occurrence at a number of additional localities were recorded during the season of 1913, by Mr. B. Rose, of the Geological Survey and the writer, brief notes of which are as follows:

Fire clay occurs on sec. 14, tp. 11, Rg. 28, west of the 2nd meridian. This deposit is situated near the north end of Lake of the Rivers, not far from the Expanse branch of the Canadian Pacific Railway, and the Avonlea branch of the Canadian Northern Railway. Lignite also occurs in this vicinity.

Greyish white, soft clay, which is very gritty, was found in sec. 30, tp. 6, Rg. 18, west of the 2nd meridian. This clay has good plasticity and drying qualities. It burns white to grey, vitrified about Cone 10, and fuses at Cone 20. This deposit is situated near Brooking, on the Canadian Northern Railway lines.

A deposit of greyish white clay with rusty lumps, which farmers in the vicinity use as a plaster, occurs on sec. 31, tp. 3, Rg. 24, west of the 2nd meridian. This clay is very plastic, stiff and sticky. Its shrinkage is rather high, and its drying qualities are unknown. It burns to a buff color, vitrifies at Cone 10, with numerous dark fused spots on surface of test pieces. It fuses at Cone 20.

A bed of light grey, highly plastic clay was found about 7 miles south of Mortlach, on sec. 17, tp. 16, Rg. 1, west of 3rd meridian. This clay is said to be about 9 feet thick. It is overlain by a thin seam of lignite, and a bed of brown clay, containing gypsum particles. It burns to a cream color at lower temperatures, and becomes grey at high temperatures. It is vitrified at cone 9, and fuses at about cone 20. It resembles a stoneware clay, being very smooth and plastic, but the shrinkages in air-drying and burning are rather high.

Some samples of semi-refractory clay from southern Saskatchewan were sent to the clay-testing laboratory for examination. The amounts of clay sent were small, and no data was given regarding quantity or distribution of the deposits. One from the banks of the Frenchman River, near Eastend, resembles a stoneware clay, as it has good plasticity, rather smooth and burns to a grey vitrified body at cone 5. It fused at cone 15.

A small sample of clay was received from one of the smaller areas of the Laramie formation, north of the south branch of the Saskatchewan, sec. 17, tp. 21, Rg. 10, west of the 3rd meridian. This is the first specimen to be recorded from this area. It is a greyish white, rather sandy clay, with good plasticity and working qualities. It burned to a grey vitrified body at cone 9, and fused at cone 20. No information was received regarding the extent of the deposit or its distance from the nearest railroad.

Several samples of easily fusible, red burning clays were also collected at various localities from the Laramie formation in southern Saskatchewan. Most of these are open to objection on account of their poor drying qualities, and excessive shrinkages. It is possible that some of them can be used when mixed with the grey burning semi-refractory clays to produce bodies suitable for sewer pipe, face brick or fireproofing.

A sample of Pleistocene surface clay was received from Davidson, on the Regina branch of the Canadian Northern Railway. This clay cracked so badly in drying that it cannot be used for brick-making by any of the ordinary processes.

An effort will be made to use this clay by what is known as the ante-fired process, which consists in first calcining the clay in heaps as it comes from the bank. The calcined clay is ground in dry pans, mixed with a small percentage of lime, pressed into brick shapes, which are hardened in cylinders under a pressure of 120 pounds of steam. The method of procedure after the burned clay is ground is the same as in making sand lime brick. This process is in the experimental stage at present, but it may provide a way for using those clays which crack in drying.

Drying defects in clays are a serious difficulty in many of the Saskatchewan localities, and is one of the reasons that there are no brick plants along the main line of the Canadian Pacific Railway in this province. The probable cause of this defect, and a method of treatment to overcome it, was given in one of the reports of the Geological Survey.*

Alberta.—Our investigations up to the present time, have succeeded in recording the occurrence of fire clays only at one locality in this province. It is possible that fire clays, similar to those in Saskatchewan, will be found in the small area of the Laramie formation which extend into the southeastern portion of Alberta when the line of the Weyburn-Lethbridge branch of the Canadian Pacific Railway, now under construction, reaches that locality. Only a few places in Alberta were visited during the limited time at my disposal this season, which will be referred to briefly.

The occurrence of white clay near Nevis on the Lacombe branch of the Canadian Pacific Railway, was brought to my attention earlier in the season by Mr. J. O. Williams, of Camrose. This deposit was visited and samples collected for testing.

The material is a hard white or light grey shale about 4 feet in thickness. It is overlain by impure brown clay and underlain by grey shale impregnated with "bentonite."

The white shale is extremely plastic when ground and mixed with water, and cracks on drying.

It burns to a white to grey body, vitrifies at cone 9, and fuses at cone 16. It is not a fire clay.

The margin of the Porcupine hills nearest to the town of Macleod was also examined, and samples taken from 3 outcrops of shale at different levels. None of these proved to be refractory when tested.

A further examination was made of the shale deposits at Didsbury. The samples collected at this point were

*Preliminary Report of the Clay and Shale Deposits of the Western Provinces, Chapter III.; Part II. Clay and Shale Deposits of Western Provinces, Chapter III.

*Clay and Shale Deposits of the Western Provinces, Part II., Chapter VII.

satisfactory with regard to their working and burning properties, but a complete section of the beds could not be obtained.

It is impossible to state whether there is a workable body of shale or whether the sandstone beds were in excess.

These shales are in the Paskapoo formation, which yields the best material so far found in the province for the manufacture of wire cut brick, face brick or fireproofing.

Four samples from the clays and shales of the coal measures at Castor, sent to the laboratory for examination, were found to be defective in their drying qualities. These were from the Edmonton formation.

Drying defects in the clays of both the Edmonton and Belly River members of the Cretaceous are quite common. A drying test should always be made in the preliminary examination of these materials. A chemical analysis of a clay or shale is useless, the physical tests are the only guide to their value.

Athabasca River.—The following notes refer to some samples of clay collected by Mr. Sidney Ells, who examined the deposits of tar sands in Northern Alberta during last summer.

It may be noted that the clays secured were merely small samples from the surface of outcrops. During the warm weather bitumen and lighter oils seep out of the overlying tar sands, and run down more or less over the underlying strata. It is, therefore, possible that the body of these clays may be free of the contamination that exists on the outcrop from this cause.

An effort will be made during the coming field season to secure larger and more representative samples of these clays.

Lab. No. 187.—Dark grey, nearly black clay underlying bituminous sand on Moose River.

This clay is very plastic, fine grained, and smooth. It works up rather stiff and slightly sticky. Dries very slowly, with a drying shrinkage of 6.5%. This clay contains such a large percentage of asphaltic carbon that it is very hard to burn without swelling, unless burned very slowly during the oxidation stage. The density of body, due to the extreme fineness of grain, interferes with the expulsion of carbon, so that the oxidizing process of this clay is tedious.

The clay burns to a light red color at the lower temperatures, and to a buff or grey at higher. It vitrifies about cone 5, and is fused at cone 20.

This clay is of the stoneware type, but the carbon it contains is a detriment.

Lab. No. 188.—From east bank of Athabasca River, ⅓ mile above McMurray, Alta.

A dark grey clay, exceedingly plastic, and smooth, smelling strongly of asphalt when damp.

It burns to a light red color at a low temperature, becoming grey when heated up to cone 5 or thereabouts.

It fuses at cone 16.

Owing to its fineness of grain, and the fact that it contains a certain percentage of asphaltic carbon, this clay is very hard to burn. It could not be used unless a certain amount of it were calcined, ground, and added to the raw clay. This would improve its working, drying and burning qualities.

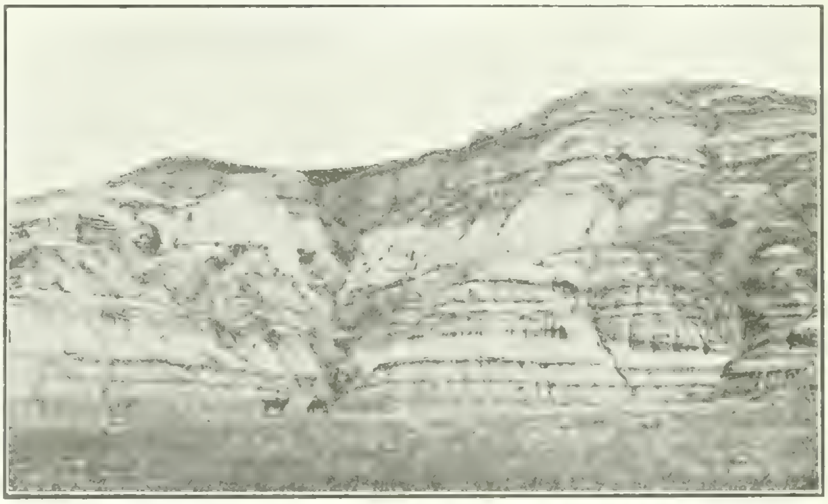
Lab. No. 190.—From point on N.W. shore of Muskeg River, between head of portage and mouth of river.

A light grey, very plastic clay, with good working and drying qualities. It burns to a cream colored, dense, steel-hard body at cone 3, with a total shrinkage of 9%, and softens when heated up to the temperature of cone 27. This is a good example of a stoneware clay, and is also a fire clay. It is the most refractory clay at present known to occur in the province of Alberta.

Lab. No. 191.—From Moose River, interbedded between bituminous sand and Devonian limestone.

Dark grey, very plastic, smooth, fine grained clay of the stoneware type. Burns to a salmon colored dense body at cone 3, with rather high shrinkage, and fuses at cone 18.

Summary.—These four examples of clay are alike in many of their physical characteristics, and appear to occur in the same geological horizon, viz., underlying the tar sands, on the Athabasca River, and its tributaries.



Typical example of clay and lignite beds in valley of Big Muddy River, South Saskatchewan.

They are very fine-grained sediments, and low in fluxing impurities, No. 190 being exceptionally so, hence they are more refractory than any of the Cretaceous clays from the southern part of the province.

The samples were too small in size to allow of complete determinations concerning their working and drying qualities, but they appear to be free from the drying defects so common to the western Cretaceous clays.

These clays are of the stoneware type, being exceedingly plastic, and burning to a light colored dense body at cone 5, while they retain their shape without softening when fired to much higher temperatures. Their most serious defect is due to the presence of asphaltic carbon, which renders the safe burning of wares made from them a difficult process. Nos. 190 and 191 appear to be free from this impurity, as far as could be told from the small samples, and these clays would be valuable for many purposes.

Owing to their position under heavy overburdens, and the remoteness from transportation at which these deposits occur, it is doubtful if they can be included in the economic resources of the region, at least for some time to come.

CRITICAL LOADS FOR IDEAL LONG COLUMNS.*

By Arthur Morley.

THE usual process of obtaining Euler's value of the critical load for the ideal case of a long, straight, axially loaded column of uniform cross-section is well known. It consists: (1) In writing from the simple theory of flexure the differential equation to the curve of bending in terms of the load, dimensions, modulus of elasticity of the material, and an arbitrary deflection at some selected cross-section of the column. (2) In solving the equation in conformity with the assigned end conditions of the column, thus deriving a general expression for the deflection. (3) In equating the appropriate value of this general expression to the arbitrary value previously assumed at the selected cross-section and solving for the value of the load.

For the third step we may, of course, substitute the method of equating the elastic strain energy of the column to the work done by the load in producing the deflection. If we use the correct form of curve, the result will be identical with that obtained from an equation of lateral displacements, but the work involved would be greater, and this latter alternative therefore offers no advantages to the designer.

Now, if we assume a general form of deflection and represent it by an algebraic expression, and use this in an equation of displacements or in the equation of work, we shall obtain a value of the critical load. Whether the value so obtained is, or is not, a good approximation to the true critical load depends mainly on whether the assumed form of deflection is, or is not, a good approximation to the true curve. For example, taking the fundamental case of a column of length l, fixed in direction at one end and quite free at the other, the deflection at a distance x from the free end bears to that at the free end a ratio of $1 - \sin \frac{x}{l} \frac{\pi}{2}$; this curve lies fairly close to that taken up by a corresponding cantilever transversely loaded at its free end, which gives a deflection $\frac{(l - x)^2 \, (2l + x)}{2l^3}$ of that at its free end, and if this latter form be assumed for the column deflection, a good approximation to the critical load will result. But in the case of a column which tapers from the fixed end to a very much smaller section at the free end, the corresponding assumption is not a safe one, and will lead in some cases to an enormous over-estimate of the critical load. The assumption of a curve flatter than the true form leads to over-estimates of the load, and that of a form of exaggerated general curvature leads to under-estimates.

Method of Successive Approximation.—The following method may be applied to struts of any kind, whether uniform, in cross-section, or otherwise; for the purpose of explanation, the case of a column fixed at one end and free at the other will suffice, but there is no limitation to the type of end condition in the application of the method.

As a first approximation, assume any deflection of the free end, and any simple form of flexural curve connecting the free and the fixed ends—even a straight line, however impossible as a final result—will serve in the first instance as a good starting-point.

*Reproduced from April 24th issue of Engineering (London).

Secondly, use the assumed form of deflection in place of the unknown form in the differential equation to the curve of bending. Thirdly, by two integrations, with due regard to the end conditions for the determination of the constants of integration, obtain a general expression for the deflection at any cross-section of the column. Fourthly, equate the resulting deflection at the free end to that previously assumed, and solve for the load. This is the approximate solution previously described, and may be called a first approximation. Next write the general expression for deflection in terms of the derived value at the free end; this is a second approximation to the true form, and if treated in the same way as the first approximation will yield a third approximation, and so on indefinitely, each step yielding in general a new flexural form and a new value of the critical load. Successive values, after a few repetitions, tend noticeably towards a fixed limit, and this is the true critical value. It is quite easy to obtain a good approximation from a straight line as a first approximation; this gives a linear distribution of bending moment corresponding to a cantilever with a transverse end load, so that the second approximation starts with a curve corresponding to the cantilever curve. Particularly with such a simple initial assumption, it will generally be noticed that the successive coefficients in the critical loads are falling into an ordered sequence, and that after a few integrations the coefficients for further approximations may be picked out by inspection from the sum of a series. By proceeding to the limiting value for an indefinitely great number of repetitions, which may be

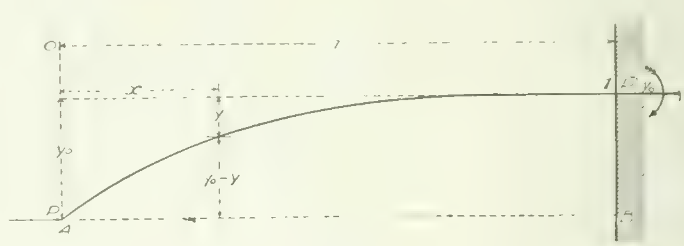


Fig. 1.

quite easy to determine, we may be able to write down an exact, instead of an approximate, value for the critical load.

For a strut, the cross-section of which changes from point to point along its axis by any but a simple continuous law, the determination may conveniently be carried out graphically. Any deflection curve initially assumed constitutes on a base-line through the free end parallel to the original direction a curve of bending moments ($M = P\,(y_0 - y)$, Fig. 1) for the strut under the action of the thrust, and well-known graphical processes give the resulting deflections. An equation of displacements then gives the first approximation to the critical load. The resulting curve of deflections may in turn be similarly treated to give a second curve, and so on until reasonable constancy is attained. Whether the treatment be graphical or algebraic, if the arbitrary choice of a first deflection curve should happen to correspond to the true form, the second form will exactly correspond to the first, and exact repetition will follow as often as the process is carried out.

The following examples illustrating this method are worked out for the case of a column fixed at one end and quite free at the other; from this case other important ones can be simply deduced by well-known relations. The first example is worked in some detail.

Notation.—Let o, Fig. 1, be the origin at the undisturbed position of the free end of the strut, x be the distance along the strut, and y the deflection. Let the suffix 1 refer to the fixed end, and the suffix o to the free end. Let l be the length of the column, I the moment of inertia of its cross-section about a central axis in its plane, and E be Young's modulus of elasticity for the material, and P be the axial thrust at the free end.

Then, in all cases the equation of simple bending is:

$$E\,.\,I\,.\frac{d^2y}{dx^2} = P\,(y_0 - y). \qquad (1)$$

Example I.:—

Let the column be of uniform section—i.e., I = constant.

First Approximation.—Assume the deflection to be along a straight line 1 A (Fig. 1)—i.e.:—

$$y = \frac{l-x}{l}\,y_0, \text{ or } y_0 - y = \frac{x}{l}\,.\,y_0. \qquad (2)$$

Then equation (1) becomes:—

$$E\,I\frac{d^2y}{dx^2} = P\,y_0\frac{x}{l} \qquad (3)$$

Integrating twice under the condition $\frac{dy}{dx} = 0$, and $y = 0$ at the fixed end—i.e., when $x = l$.

$$E\,I\,y = \frac{P\,y_0}{2\,l}\left(\frac{1}{3}x^3 - l^2x + \frac{2}{3}l^3\right) \qquad (4)$$

and at $x = 0$,

$$E\,I\,y_0 = \frac{P\,.\,y_0\,.\,l^3}{3} \qquad (5)$$

from which the first approximation is:—

$$P = \frac{3\,E\,I}{l^2} \qquad (6)$$

Second Approximation.—Dividing (4) by (5),

$$y = y_0\left(\frac{1}{2}\frac{x^3}{l^3} - \frac{3}{2}\frac{x}{l} + 1\right) \qquad (7)$$

which is the form for a cantilever with a transverse end load, as might be foreseen from (3), in which the bending moment is proportional to x; when known it might be chosen as a starting point instead of the simpler form (3), which does not comply with the condition $\frac{dy}{dx} = 0$ for $x = l$. Using the form (7) in (1),

$$E\,I\frac{d^2y}{dx^2} = P\,y_0\left(\frac{3}{2}\frac{x}{l} - \frac{1}{2}\frac{x^3}{l^3}\right) \qquad (8)$$

whence, proceeding as before,

$$E\,I\,y = \frac{P\,y_0}{40\,l}\left(10\,x^3 - \frac{x^5}{l^2} - 25\,l^2x + 16\,l^3\right) \qquad (9)$$

and

$$E\,I\,y_0 = \frac{16}{40}\,P\,l^2 \qquad (10)$$

$$P = 2.5\,\frac{E\,I}{l^2} \qquad (11)$$

Third Approximation.—Dividing (9) by (10),

$$y = y_0\left(\frac{5}{8}\frac{x^3}{l^3} - \frac{1}{16}\frac{x^5}{l^5} - \frac{25}{16}\frac{x}{l} + 1\right) \qquad (12)$$

And again substituting in (1),

$$E\,I\frac{d^2y}{dx^2} = \frac{1}{8}P\,y_0\left(\frac{1}{2}\frac{x^5}{l^5} - 5\frac{x^3}{l^3} + \frac{25}{2}\frac{x}{l}\right) \qquad (13)$$

from which,

$$E\,I\,y = \frac{1}{32}P\,y_0\left(\frac{1}{21}\frac{x^7}{l^5} - \frac{x^5}{l^3} + \frac{25}{3}\frac{x^3}{l} - \frac{61}{3}\,l\,x + \frac{272}{21}\,l^3\right) \qquad (14)$$

$$E\,I\,y_0 = \frac{1}{32}P\,y_0 \times \frac{272}{21}\,l^2 \qquad (15)$$

$$P = \frac{42}{17}\frac{E\,I}{l^2} = 2.4706\,\frac{E\,I}{l^2} \qquad (16)$$

The successive approximations are $E\,I \div l^2$ multiplied by 3, 2.5, 2.4706, 2.4677 . . . etc., where the true coefficient is well known to be $\frac{1}{4}\pi^2 = 2.4674$ . . .

Each successive approximation for y approaches more nearly the true value—viz., $y_0\left(1 - \sin\frac{x}{l}\,.\,\frac{\pi}{2}\right)$.

Thus the true value at $x = \frac{1}{2}\,l$ is $y\left(1 - \frac{1}{\sqrt{2}}\right) = 0.293\,y_0$, whereas (2), (7), (12) give respectively $0.5\,y_0$, $0.3125\,y_0$, $0.295\,y_0$. The successive curves are each flatter than the true curve, and give a value of P in excess of the true value.

An alternative to the form (2) would have been to assume a parabolic curve:—

$$y = \frac{(l-x)^2}{l^2}\,.\,y_0 \qquad (17)$$

which satisfies both $y = 0$ and $\frac{dy}{dx} = 0$ for $x = l$. In this case the successive approximations are $\frac{E\,I}{l^2}$ multiplied by the factors 2.4, 2.4590. These are below the true value $\frac{1}{4}\pi^2$; correspondingly the values of y indicate more curvature than in the true sine form. For $x = \frac{1}{2}l$, (17) gives $y = 0.25\,y_0$, and the second approximation gives $y = 0.2875\,y_0$, as against the above true value $0.293\,y_0$.

The form (17) is the curve taken by the column under the action of a couple at its free end. This will, with any type of column, give a curve of exaggerated curvature and an approximation on the safe side, to the critical load. It will also provide a starting-point for approaching the true limit from the safe side. By starting from both sides it is more easy to judge the value of the limit from a very few trials when the limit is approached slowly.

Example II.:—

Let I vary as the distance x from the free end—i.e.:

$$I = \frac{x}{l}\,I_1 \qquad (18)$$

First Approximation.—Assuming the form (2) equation (1) becomes:—

$$E\,I_1\frac{d^2y}{dx^2} = P\,y_0 \qquad (19)$$

which gives:—

$$y = \frac{P\,y_0}{2\,E\,I_1}(x-l)^2, \text{ and } y_0 = \frac{P\,y_0\,l^2}{2\,E\,I_1} \qquad (20)$$

Hence

$$P = \frac{2\,E\,I_1}{l^2} \quad . \quad . \quad (21)$$

Second Approximation.—

$$y = y_0 \frac{(x-l)^2}{l^2} \quad . \quad . \quad . \quad (22)$$

when substituted with (18) in equation (1) gives:—

$$E\,I_1 \frac{d^2 y}{d\,x^2} = P\,y_0 \frac{2\,l - x}{l}. \quad . \quad . \quad (23)$$

Two integrations then give:—

$$y = \frac{P\,y_0}{E\,I_1\,l}\left\{-\tfrac{1}{6}x^3 + l\,x^2 - \tfrac{3}{2}\,l^2\,x + \tfrac{2}{3}\,l^3\right\} \quad (24)$$

$$y_0 = \frac{P\,y_0\,l^2}{E\,I_1} \times \tfrac{2}{3} \quad . \quad . \quad . \quad . \quad . \quad (25)$$

$$P = \tfrac{3}{2}\frac{E\,I_1}{l^2} \quad . \quad . \quad . \quad . \quad . \quad (26)$$

The successive factors of $\frac{E\,I_1}{l^2}$ in the values of P are 2, 3/2, or 1.5, 16/11 or 1,45, 495/341 or 1.4516. ∴ . The assumption (17) is identical with (22), and leads to the same series of approximations.

The limit is in this case approached so rapidly that $P = 1.45 \frac{E\,I_1}{l^2}$ may be taken as a good approximation.

Example III.:—

Let I vary as the square of the distance from the free end—i.e.:—

$$I = I_1 \frac{x^2}{l^2} \quad . \quad . \quad . \quad (27)$$

Following the method of the previous examples, the successive coefficients of $\frac{E\,I_1}{l^2}$ in the values of P are 1, ½, 2/5, 5/14, 1/3, 7/22, . . . etc.

Here the limit is approached much more slowly, and evidently the first two approximations are very bad and yield very incorrect value of P on the unsafe side. From the way in which the coefficients develop in the integrations (which would take too much space to reproduce in full) it becomes evident that successive values may be written from the numbers in Table I., overleaf. These numbers are interesting and very simply related; the constitution of the first two lines is obvious, and the lowest number in each column is a repetition of the one above it. All rows after the first may be written by making each number the sum of that above and that to the left of it.

Successive approximations to the coefficient of $\frac{E\,I_1}{l^2}$ are obtained by dividing the sum of any column by the sum of the succeeding column; for the word "sum" "last number" may be submitted, since the last term in any column is equal to the sum of the previous column. To reach any degree of approximation is now only a question of simple arithmetic, but we may algebraically proceed to the limiting value of the coefficient. The successive numbers in the $(n+1)$th column are:—

$$1,\ n,\ \frac{n(n+1)}{1.2} - 1,\ \frac{n(n+1)(n+2)}{1.2.3} - 2,$$

$$\frac{n(n+1)(n+2)(n+3)}{1.2.3.4} - \frac{n(n+1)}{2} - 2n - 3, \text{ etc.}$$

The nth number is

$$\frac{n(n+1)(n+2)\ .\ .\ .\ .\ (2n-3)(2n-2)}{n-1} -$$

$$\frac{n(n+1)(n+2)\ .\ .\ .\ .\ (2n-4)}{n-3} - 2\,\frac{n(n+1)(n+2)\ .\ .\ .\ .\ (2n-5)}{n-4}$$

$$-\,3\,\frac{n(n+1)(n+2)\ .\ .\ .\ .\ (2n-6)}{n-5}, \text{ etc.,}$$

$$-\,\frac{(n-5)(n+2)(n+1)n}{1.2.3} - \frac{n(n-4)(n+1)n}{1.2}$$

$$-\,(n-3)\,n - (n-2).$$

Taking the ratio of the nth number of the $(n+1)$th column to the $(n+1)$th number of the $(n+2)$th column, and proceeding to the limit in which n is indefinitely great, we find the limiting value of the coefficient to be ¼.

If we assume the form (17) as a starting point, the successive approximations to the coefficient of $\frac{E\,I_1}{l^2}$ are ⅔, 6/13, 26/67, 134/381, etc., for which a table may be constructed to give further approximations by arithmetic; the table is not quite so simple as Table I., but gives, of course, the same limiting value, and the alternative offers

Table I.

	1	1	1	1	1	1	1	1	1	1
		1	2	3	4	5	6	7	8	9
			2	5	9	14	20	27	35	44
				5	14	28	48	75	110	154
					14	42	90	165	275	429
						42	132	297	572	1,001
							132	429	1,001	2,002
								429	1,430	3,432
									1,430	4,862
										4,862
Totals	1	2	5	14	42	132	429	1,430	4,862	16,796
Coefficients of $\frac{E\,I_1}{l^2}$	1	$\frac{1}{2}$	$\frac{2}{5}$	$\frac{5}{14}$	$\frac{14}{42}$	$\frac{42}{132}$	$\frac{132}{429}$	$\frac{429}{1,430}$	$\frac{1,430}{4,862}$	$\frac{4,862}{16,796}$
Coefficients as decimals	1	0.5	0.4	0.3571	0.3333	0.3182	0.308	0.300	0.2941	0.2894

no advantages. By modifying a numerical coefficient in, say, the second approximation for y, we may bring the resulting value of the coefficient of $\frac{EI_1}{l^2}$ near or exactly to $\frac{1}{4}$, but the succeeding values will go away from the true coefficient, and then gradually approach it again, so that the simplest assumption (2) appears to be as good as any other. This example scarcely represents a type of practical column, but it illustrates well the method of successive approximation and the entire unreliability of the early approximations in certain cases of columns of variable section. Its exact solution may be obtained from the differential equation (1), which, with (27), becomes—

$$x^2 \frac{d^2 y}{d x^2} + \frac{P l^2}{E I_1} \cdot y = \frac{P l^2}{E I_1} y_0 \quad . \quad (28)$$

The solution under the assigned conditions is—

$$P = \frac{1}{4} \frac{E I_1}{l^2} \text{ and}$$

$$y = y_0 \left(1 - \sqrt{\frac{x}{l}} - \frac{1}{2} \sqrt{\frac{x}{l}} \log \frac{x}{l} \right) \quad . \quad . \quad (29)$$

a value which will, of course, repeat itself after a succession of integrations of equation (1). How greatly the second value of y, which is—

$$y_0 \left(\frac{x}{l} \log \frac{x}{l} - \frac{x}{l} + 1 \right) \quad . \quad . \quad (30)$$

corresponding to the end loaded cantilever curve, differs from (29) is evident by comparing the values of y for, say, $x = \frac{1}{3} l$; the form (29) gives $y = 0.105 y_0$, while (30) gives $y = 0.301 y_0$.

The weakness of this column lies in the flexibility of its free end, which would also reach the elastic limit before the critical load, unless modified in shape.

(To be continued.)

A NEW ELECTRICAL DIRECTORY.

The McGraw Electrical Directory.—The last semi-annual issue of the McGraw Electrical Directory has been received. This very useful book contains a list of central stations in the United States, Canada and Mexico, giving for each station full particulars of equipment, personnel of operating force, ownership, etc. This issue gives the details of 434 Canadian companies, including municipal systems. This list includes nine companies that have been organized since the publication of the last half-yearly list. The total number of generating stations in Canada is 402, not including substations. The number of companies purchasing energy is 28, while there is an equal number of municipal systems purchasing energy. There are 175 municipal lighting systems. In Canada, electrical supplies are carried by 244 of the firms or municipalities. Much other useful information is also contained in the volume, which is 726 pages, size 4¼" x 8½". The price of the Directory is $5.00, and it can be ordered through the Canadian Engineer Book Department.

A Chicago report of June 6 states that the plans for that city's new west side terminal railway station have been approved by the Illinois public utilities commission.

A recent report from New York states that the New York Central lines have contracted for 7,300 freight cars. This order is the largest since the purchase of 12,000 cars last year by the Pennsylvania lines. The New York Central has divided its order between the American Car and Foundry Company and the Standard Steel Car Company, the former to supply 4,300 cars, and the latter 3,000 cars.

UNIT PRICE vs. LUMP SUM CONTRACTS.

MANY arguments have been advanced to uphold the advantages and disadvantages of the various methods in vogue by which the contractor receives his remuneration for work which he has undertaken to do. It is generally understood that there are imperfections connected with each, but that under certain conditions one may be considerably better than another. In a paper which he read last fall at the 10th annual convention of the American Road Builders' Association in Philadelphia Mr. H. C. Hill brings forth a number of arguments in favor of the unit price method, and attempts to prove that in the majority of cases contract work on this basis is the correct method. He argues that percentage work is nothing more than day labor, so far as the cost of manual work is concerned. It differs in total cost only in that there is at the start an organization with a certain knowledge of how the work should be laid out and executed, directed by a man or firm whose reputation for doing work at a reasonable cost is at stake.

The following is a portion of Mr. Hill's paper:—

Contract work has every advantage that percentage work has, and something in addition, namely, an incentive, which constantly spurs every man, to a more or less degree, depending upon his nature, to do the work set before him in the most economcial manner and with the least expenditure of energy. Some will say that this is too true and leads in a few cases to poor work. If this is so, it is not the fault of the method, but the fault of those doing the work, more particularly those having supervision; for it is possible to eliminate entirely those contractors who desire only to make as large a profit as possible, irrespective of the class of work done—and it has been done.

An attempt has been made to instill "incentive" into percentage work by establishing a price on each unit of work and paying a bonus on a sliding scale if the work is done at a cost less than that first agreed upon. This is a very delusive point, and those familiar with the variable factors in cost data will readily see the futility of it. Furthermore, it will not take much of a mathematician to figure that it is the percentage and not the bonus that gives the contractor his profit, unless the agreed price is considerably higher than the actual cost should be. It being true, then, that percentage work tends to increase the cost of the work, there remains the question of under what method of payment contract work shall be done.

In comparing the advantages and disadvantages of lump sum and unit price contracts, it is possible to consider them under two heads, namely, the engineering feature and the moral aspect.

The point upon which the advocates of the lump sum method lay the greatest stress is that the cost of work is reduced by having the engineering charges a minimum. Those of this opinion are wont to tell how much cheaper work is done, basing their comparison on an average cost—as in highway construction the average cost per mile—instead of basing the comparison upon the actual amount of material moved or used. The truth or falsity of this statement is not subject to any specific proof, for it is impossible to have the same piece of work done by both methods, but it is subject to proof in a general way. A very close approximate might be obtained, if desired, by procuring bids for the same piece of work on each method, then after the completion of the work comparing the average of all the lump sum proposals with the average total of the unit price proposals,

using, however, as a basis for the latter, not the actual unit quantities as shown by a final estimate, but the bidding schedule quantities. This is, perhaps, more theoretical than practical, but satisfactory proof that under lump sum contracts the work costs more is furnished by the fact that no reliable, experienced contractor will bid as low on a lump sum proposal as he will if the work is to be let on a unit price proposal. This is a definite statement, but one which a majority of contractors will agree to, and for this reason: Contract work in any form contains certain factors the exact nature of which it is impossible definitely to determine until after they are encountered, and every contract, except it be a percentage contract, must necessarily be more or less of a gamble. Therefore, no contractor overlooks this factor —and you can rest assured that the larger the risk the higher the bid. This element of risk is less on a unit price contract than on a lump sum; for under the former, should a certain class of work increase over the estimate, the contractor gets a corresponding increase in pay, and should less work be done he gets a corresponding decrease in pay. Under the lump sum method such changes have no effect upon the amount of money received by the contractor for doing the work.

In some cases under lump sum bids, estimates for the various quantities are prepared, but the general practice is for the bidder to ascertain these for himself, either by his own engineer or by guess based upon general knowledge. Even in cases where careful estimates are prepared, the final quantities are not the same as those upon which the bid was made out; therefore, as far as payment is concerned under this method, estimates are of no positive value. The fact, however, that there is a variance between the preliminary and final estimates is not the fault of an engineer, for it is impossible to determine accurately the exact quantities until the work is completed.

The theory of the unit price method is a very simple and just one. Expressed in a few words it conveys this idea: The contractor is to be paid for just what he does and to do just what he gets paid for. Nothing could be more equitable than this. However, like everything else, it has its imperfections, but not of a very serious nature. Its weakness lies not in itself, but in the hands of inexperienced men, incapable through ignorance of properly preparing unit quantities. This weakness causes what is known as unbalanced bidding, and consists of bidding high on items the estimate of quantities of which in a contractor's judgment is lower than will be used, or vice versa, and so regulating his bid on these items that he will lower his total bid and at the same time increase the aggregate amount he will receive for doing the work. This results sometimes in putting an engineer in an embarrassing position. Those who condemn this method should ask themselves if an unbalanced bid is any worse than an unbalanced bidding schedule prepared by engineers, and if criticism of unit price contract methods is not primarily due to those who make the estimates and not to the contractors. If engineers were as careful not to leave any loopholes in preparing estimates for contractors to bid on as they are making out specifications for doing the work, unbalanced bidding would become almost an unknown quantity.

Another advantage of having work done by unit prices is that it enables changes to be made while the work is in progress with the least possible chance of any dispute, and as a rule at a less cost than by the lump sum method. Oftentimes such changes are to the disadvantage of the contractor, but the majority of them realize that the changes are necessary for the proper [illegible] of the work; and so much more satisfactory to them are unit prices that they prefer to do work by this method, submitting willingly to such additions or deductions as may be found necessary while the work is in progress. While changes are, of course, possible under the lump sum method, so much is involved that only as the last resort is any change made. This is unfortunate, for often during construction it is possible to make some alteration that will improve the work and perhaps save more than the total engineering expense of having the work done on a unit price basis.

Great as are the advantages of the unit price contracts, viewed from the engineering standpoint, they are even greater from the moral standpoint. To make money is obviously the principal object of every contractor who earns a living by his work. The word "principal" is used instead of "first" to differentiate. His first object should be to do as good work as is intended by the specifications. It is, however, the nature of many people not to do the task set before them in as careful, thorough and complete a manner as desirable. In this respect contractors, and more particularly their employees, are not unlike others; hence the importance of any method of payment that will remove the temptation to do poor work. It needs only a superficial examination of a lump sum contract to see that not only is the incentive to do faithful work absent, but there is also a premium for not doing it.

STEEL DIRECT FROM ORE.

Now that modern conditions demand such severe specifications for steel, it is an undoubted fact that the steelmaker is experiencing greater and greater difficulty in meeting these demands. The difficulties experienced in eliminating such impurities as oxygen, phosphorus, sulphur and silicon, and the practical failure to eliminate nitrogen and hydrogen, have naturally led to a search for a method of manufacture with which a purer steel could be more readily obtained. An account of some experiments to this end were given at a meeting of the Iron and Steel Institute of Great Britain recently. An electric furnace was selected, the ease with which it can be controlled, and oxidizing and reducing conditions obtained at will, being the chief factors influencing this decision. Three series of tests were made—viz. (a), direct reduction of silicious Swedish iron ore; (b) direct reduction of Swedish and a silicious Swedish iron ore, with 30 per cent. of scrap mixed in the charge; (c) direct reduction of Brazilian iron ore. The result was the production of a steel of great toughness, and having regard to the fact that so much is heard of the baneful effect of nitrogen and hydrogen in steel, it is claimed as a distinct advantage of the process that these gases are never introduced into the charge. The result is that the conclusion has been arrived at, by those who carried out the experiments, that with the aid of the modern electric furnace, and given satisfactory conditions, the economic manufacture of steel direct from ore is a practical possibility. It is suggested that a special type of Héroult furnace will be developed for the purpose, and probably the best use for the process will be found in countries which possess readily available sources of water power, together with deposits of pure rich ores. There is considerable scepticism, however, on the part of many as to the possibility of making any such process a commercial success. That steel can be manufactured in this way is not denied, but its manufacture on a competitive commercial scale, except for very special purposes, is seriously doubted. The fact that it has been tried before and failed, however, does not necessarily prove conclusively this argument.

The annual report of the Department of Mines of the Dominion Government declares that "the district between Regina and Moose Jaw, and the district along the Alberta boundary in Saskatchewan is reported to offer a chance for oil operations." It is rumored in Regina that an oil expert will investigate the matter in the near future

Editorial

MECHANICAL TREND OF ROAD CONSTRUCTION.

The problems which the development of mechanical traction upon our highways has occasioned are manifestly well distributed. The financing, engineering and construction phases of road building are each effected in relatively proportionate ways. Greater expenditure upon construction and maintenance for the first, changes in design and materials attended by new forces, and to be solved under more stringent conditions than formerly, for the second; and changes in the method of carrying out these plans and designs, in the case of the third, have produced three-cornered problems coincident and interdependent upon each other.

The greatest changes, however, have transpired in the methods of construction. The production of labor-saving machinery and equipment, in evidence wherever there is a road development or organization, has created a necessity for expert attention and care, in order that this machinery may be efficient of operation and long of life. The situation has been well explained by Mr. H. T. Routly, well-known for his road building in Northern Ontario and in Quebec, in a paper recently presented to the University of Toronto Engineering Society. He states: "Once a system of roads has been located, designed and laid out by the civil engineer his work is practically over—except for passing the estimates of work done. The business of actual road *construction* is a question of machinery in three phases: (1) selection and purchase, (2) operation and care, (3) maintenance and repair. And here is an ever-widening and remunerative field for students and graduates in mechanical engineering, with suitable positions as stepping stones all along the line and at its best during the students' vacation season. Few of them are taking advantage of the opportunity. The positions are filled mostly by men who have graduated from a threshing engine in one season. Many have to be trained on the work without previous experience. As a matter of fact, these latter men are usually the more satisfactory, for they come admitting their inexperience and readiness to learn. They are usually very careful, and while ambitious for advancement, are more willing to earn it by strict attention to duty. But their lack of technical education is so serious a handicap that they can rarely reach the higher ground and are unable to render themselves as useful to their employers as they otherwise might.

"It is seldom that a road outfit is found under the charge of a first-class practical mechanic or engineer, and yet nowhere are his services more urgently needed. The man in charge of all such outfits, whether owned by municipalities or by contractors, should be first of all a manager of men, after that a first-class machinist, and lastly, a practical road builder. Others may arrange these essential requirements differently; all will agree about the first requirement, being the ability to handle his men; I maintain that it is easier for the machinist to acquire a thorough knowledge of practical road building than for the road builder to acquire a thorough knowledge of the machinery he is required to use. Without that knowledge he is only half efficient and is always at the mercy of and dependent upon his various machine men, his lack of such knowledge detracting from his prestige not only with the machine men themselves but with the other men as well.

Ordinarily a road outfit will be working at some distance from any machine shop where repairs can be readily obtained. The building season is short at the best, and delays for machinery repairs very expensive. The superintendent who can detect and remedy faults before they become dangerous and who can repair on the ground the ordinary breaks, is able to keep his plants working a much greater percentage of the possible working time and to save a larger proportion of maintenance and depreciation charges than the superintendent who lacks the thorough knowledge of his machinery.

"PRACTICAL" AND "THEORETICAL" DESIGNING.

In *The Canadian Engineer* for June 4th, 1914, appeared an article entitled "Practical Design of Steel Structures." The writer, as the title suggests, is emphatic in his estimation of the value of "practical" compared with "theoretical" design. Some interesting comments upon the paper have appeared in a recent issue of "Engineering and Contracting," which will be found interesting, no doubt, by many who had read the article referred to. Our contemporary emphasizes the absurdity of any division of the subject into two classes: "practical designing" and "theoretical designing," as follows:

One is just as "practical" as the other, and neither is "theoretical" (which means not practical or depending on theory). The making of preliminary plans most certainly should be in charge of a man who is essentially practical. . . . We believe that it is a mistake to attempt to set apart, arbitrarily, one branch of engineering design as "theoretical," and assign to it men who have received training in our engineering schools, and another branch as "practical," and to place in charge of it men who have gained their entire knowledge of engineering from the school of experience. Either type of man may become eminently successful in any branch of engineering, provided he has the proper desire and ability to learn and the necessary application. To be successful in any branch of engineering one must be essentially practical, and this quality cannot be measured by the fact that a man has or has not received training in an engineering school. Such a training, however, we believe is advisable.

The field of engineering has broadened so much in the last twenty years, that it is no longer possible to say just what it includes or excludes. It has no hard and fast line of limitation, nor yet are the lines of division between its various branches quite distinct. This is a condition which has had to be met, in the education of the young engineer, by drafting into the university, as teachers, men of high professional standing from the world without. Such men are best capable of giving useful instruction in theory, and demonstrating, by live examples from the field, how and where theories apply in practice. They have come to possess, moreover, through the ups and downs of their experience, a keener and warmer sympathy for the student in the profession.

ROAD PRACTICE IN BIRMINGHAM, ENG.

SOME interesting references to methods of road construction and maintenance in Birmingham, Eng., were brought out by Mr. H. M. Lawson, Deputy Road Surveyor for that city, in a paper read on March 5th, 1914, at a meeting of the Institution of Municipal and County Engineers. Mr. Lawson's paper dealt with water-bound macadam, tar-spraying, asphalt macadam, sett-paving, sheet asphalt, and street-cleaning. The following notes, dealing with several of these, are abstracted from his address:—

In many instances water-bound macadam roads are condemned as useless under average traffic conditions; the chief reason for this is that in many cases these roads have no foundations or proper drainage. Therefore it is of great importance to get a solid and well-drained foundation, and adequate surface drainage; also to ascertain that every care has been taken to decide the wearing qualities of the stone employed, and to ensure that it is of one uniform quality. It is obvious to any road enginer that, wherever one has stones of different qualities (and this applies also to stone-sett and wood paving), the softer stone soon begins to show itself by wearing down below the harder, resulting in a series of up and downs.

The city engineer of Birmingham, in dealing with the construction of new water-bound macadam roads carried out by contractors, has a specification which is strictly adhered to, inspectors being appointed for the special purpose of looking after this class of work.

The form of construction is as follows: A layer of clean clinker ashes or broken stone, 6 in. in depth when rolled solid, is followed by a second layer, consisting of hand-pitched slag, 6 in. to 8 in. in depth (according to the nature of the traffic), set on edge, in the manner of a rough pavement. Over this layer a coating of broken slag or other approved material is laid, so as to fill up the interstices to form a smooth surface; each layer is thoroughly consolidated. A row of 4-in. by 6-in. granite setts on concrete is laid outside the channel stone as a margin course. The metalling for finishing the carriageway is then spread with forks in two coats. The first coat having been uniformly spread over, the whole carriageway is then rolled until consolidated. The second coat is then uniformly applied and consolidated, making a thickness of 6 in., the surface then receiving a coating of fine clippings of the same description of material as the metalling used; the chippings are screened through a ¾-in. mesh, and include the finer material, down to dust. The carriageway is then lightly watered and rolled until thoroughly consolidated, two men being engaged in sweeping the chippings into the interstices of the stone. On completion, it is coated with a thin layer of ½-in. chippings of similar material, free from dust. Each layer is laid to a camber or gradient of 1 in 25.

The author has found, in carrying out this work, that at times, unless one has been careful in choosing a sufficiently tough stone (and in some cases the cost prohibits this), the stone is broken and crumbled in the process of consolidation by steam rolling; to obviate this, a little binding material in minimum quantity is spread over the metal and slightly watered. Too much attention cannot be given to the spreading of the stone, which really requires great care and skill, as the evenness of wear of the surface greatly depends upon uniform spreading.

In Birmingham the city engineer pays a small bonus to the spreaders; this method works exceedingly well, as there is competition among the men, and only the ablest men are selected for the work. Great care must be taken to see that very little water is used, as there is a tendency on the part of rollermen to use as much as possible, to expedite rolling operations. The loading of this stone into the carts is done with forks, but in a district formerly under the author's supervision, when carting stone on to a site and tipping it close to the spreading, a difficulty was experienced owing to a thorough turning over of the material being impracticable. This was remedied by tipping the stone on to concrete mixing boards, thereby ensuring that it was properly turned, and so obviating any chance of having larger stones in some parts of the road and smaller ones in other parts, besides preventing all the dust, etc., from settling at the bottom.

The method of recoating is to scarify the crust of the old road, regulating the old material, and then applying a 3-in. coat of new metal. Generally speaking, there are two ways of repairing a macadam road, patching or recoating the whole surface. As soon as any potholes or uneven wear appears it should be attended to immediately, the cause ascertained and remedied, and the necessary repairs undertaken. If repairs are delayed it generally means that in a very short time the recovering of the whole surface is necessary, which adds considerably to the cost of repair. Any road, the crust of which is weak, will very soon become bumpy. It is most difficult to keep the surfaces of roads in good condition, owing to the various statutory authorities, such as gas and water companies, interfering with them; also by reason of the fact that in most of the main roads in this city there is a tramway track, and in many parts the sides between the track and the channel is constructed in macadam. This requires constant attention, owing to the traffic causing a rut to form next to the paving. Macadam roads are also being considerably damaged by motor 'bus traffic, and in comparing the repairs to a certain road prior to 'buses running with a corresponding period afterwards, the cost was found to be practically trebled. These motor vehicles do a vast amount of damage, particularly in roads not constructed to sustain their weight and destructive influence.

Tar-Spraying.—In treating road surfaces by the application of tar, the author has found that the life of the roads is prolonged, and also the dust nuisance reduced to a minimum. The chief object is to secure a deep penetration of tar below the surface, so that the metal may be kept together, and a road treated properly in this manner should have the appearance of a tarred-macadam road.

Last year, in Birmingham, 1,771,515 super. yds. of roads, comparable with a length of over 134 miles, were tar-sprayed. The major portion of this work was done by six 1,000-gallon machines, hauled by steam rollers, the cost per super. yard being just under a penny.

To get the best results from tarring, the surface must be thoroughly clean and dry, it being a waste of time and money to treat the surfaces of roads with tar when in a bad condition. The author has observed many failures owing to this alone, and thinks that it is obvious that by tar-spraying a bad road it cannot be converted into a good one.

Tar-spraying should be carried out in a methodical manner, all roads coated or reconstructed in the fall months being tar-sprayed in the early spring, and again, if necessary, in the early autumn. Hills having a steep gradient should be specially gritted if tar is applied to the surface.

Sett Paving.—The author is of opinion that the following describes the most serviceable form of paving for heavy traffic: 5-in. or 6-in. setts laid upon a foundation

consisting of Portland cement base concrete, 9 in. thick (6 to 1), on which is placed a bedding of slightly damped cement and sharp sand, free from silt or loam, to a thickness of 1 in. The paving should be laid before the concrete becomes too hard, when sufficiently damp or mellow enough for the 1-in. feed to unite with it. The setts should be damped with a rose water can, and then grouted with a mixture of 3 of sharp sand to 1 of cement, and rammed as soon after as possible, the whole forming a 16-in. seal of solid mass. Great care must be taken to see that the whole of the materials are thoroughly mixed and of the best quality. No traffic should be allowed over the paving for at least ten clear days.

Both cement and pitch have been used for grouting sett paving, but the author favors the former in all cases where possible, although, to meet present-day requirements, pitch grouting has certain advantages inasmuch as roads finished in this manner can be opened to traffic immediately after completion. There is also less tendency for mud to collect on this kind of grouting, which, however, must be skilfully handled to ensure the proper proportion and correct mixing of the ingredients. The method adopted by the writer is to use a grouting mixed to the following proportions: 2 to 3 gallons of creosote oil and 1 gallon of coal-tar added to every 1 cwt. of pitch. (The quantities of oil and tar being determined by the nature of the pitch.) The joints of the setts having been filled about half way up with ⅜-in. or ¾-in. pea ballast or shingle, and then rammed. Great care must be taken to see that this racking is thoroughly dry. The pitch mixture is then poured from a spouted pail into the corner of the setts (this prevents surplus being left on the top), to about half their depth, and the remainder of the joints filled up with racking as before. Sweep with hard broom and squeegee over the whole surface with the pitch mixture as quickly as possible, so as to leave the smallest accumulation on the top. On no consideration should this work be done other than when atmosphere and materials are in a perfectly dry state.

Perhaps here it might be of interest to mention a particular form of paving in which the author is concerned, which consists of specially dressed 5 in. wide by 4 in. deep Grey Royal setts, laid on a concrete foundation. The contractors were called upon to replace a considerable number of setts with broken corners. The stones were paved when wet on bedding which was more than damp, and when the stone was surface dry, boiling pitch grout was poured into the joints, with the result that it attacked the shakes or flaws in the setts, generated steam in them, and this, acting as a wedge, slightly detaching the flaw or shake portion of the sett. Under heavy continuous traffic it became wholly detached, pulverized, and peeled out. The author is of the opinion that had this work been completed with pitch grouting in dry weather this would not have happened, or, under the above circumstances, had cement and sand instead of pitch been used for grouting.

In Birmingham the standard size of setts used is 4 in. by 4 in. by 5 in. deep, laid with a crossfall of 1 in 45 from the crown of the road to channel, and in straight diagonal courses, meeting in the centre at an angle of 90 deg., with the apex pointing downhill, at an angle of 45 deg. with the channel where the kerbs are parallel. The setts are paved on a 1-in. bed of local sand grouted with a proportion of 5 parts of clean sharp sand to 2 parts of cement. The concrete bed is 7½ in. in depth, the ballast for it consisting of clean, non-porous blast-furnace slag with such an admixture of sand sufficient to fill up the interstices of the stone. After completion, a layer of clean sand is spread over the whole surface, and no traffic allowed over it for three weeks.

In this district the most suitable material for paving streets of steep gradients traversed by heavy traffic has proved to be "grit-stone," the steepest gradient paved with this material being 1 in 11. Care should be taken to see that this class of paving is constantly swilled with water so as to prevent an accumulation of mud and dirt on the surface, and if this has proper attention, complaints of slipperiness are practically unknown. In London and other cities specially dressed 5 in. wide by 4 in. deep Grey Royal setts have been laid on steep gradients, with very close joints, with much success. . . .

Cleansing.—It is obvious that road surfaces need systematic cleansing, gritting and watering, but the author would like to emphasize the trouble that has been experienced in regard to sweeping newly constructed water-bound macadam roads, for, if careful attention is not given to this matter, the binder will soon be removed. In a former district under the author's control, machine sweeping brushes were not used on water-bound macadam surfaces.

The watering of streets in any city is also of great importance, especially as there is now so much motor traffic on the roads. The author had steam motors fitted with tanks, and has found that this method is much more economical and effectual than horse-drawn water carts. These machines were fitted with interchangeable bodies, so that the motors, when not engaged for watering, could be utilized for carting stone or any other materials. In addition to these machines, a steam motor vacuum extractor was used for emptying gullies, and a considerable saving was effected, as compared with ordinary gully vans, besides being more hygienic and saving that splashing which invariably takes place when gullies are being emptied.

UNION OF CANADIAN MUNICIPALITIES.

As announced in our columns some little time ago, the 14th annual convention of the Union of Canadian Municipalities will be held in Sherbrooke, P.Q., on August 4th, 5th and 6th. A comprehensive program has been arranged, special provision being included for opportunities of discussing the numerous questions which will be presented by prominent municipal men from various parts of the Dominion. The aim of the Union, which is to afford municipal men a practical means of learning at first hand up-to-date methods of municipal government from men of experience and of affording also an effective link of municipal union and co-operation against influences adverse to the interests of the people, is certainly to be upheld and encouraged.

Among the various subjects that will be brought up for consideration are the following:—

Building Laws, Smoke Abatement, the Housing Problem in Cities, Municipal Reference Library, Playgrounds, Street Lighting, Taxation and Finance, the Wants of Rural Municipalities, Billboards and Posters, the City Manager Question, Public Libraries, Motion Picture Theatres, Street Cleaning, Water Rates, City Publicity.

The general contractors in the city of Montreal have recently formed an organization with the following officers:—President, Mr. J. P. Anglin, of Anglins, Limited; vice-president, Mr. E. G. M. Cape, of E. G. M. Cape, Limited; secretary-treasurer, Mr. W. Clement Munn, of the Atlas Construction Company, Limited; directors, Messrs. W. D. Ross, of Church, Ross and Company; Guy Boyer, of the Laurentian Construction Company; Rene Lessard, of T. Lessard, and C. Ekin, of the Geo. A. Fuller Company, Limited.

THE CALCULATION OF END AREAS.*

By E. S. M. Lovelace, B.A.Sc., M.Can.Soc.C.E.,
Civil and Consulting Engineer, Montreal.

THE following is a method of calculating end areas without any reduction of elevations or plotting of cross-sections, using direct the notes as taken in the field, thus effecting a great saving in time, giving increased accuracy, and at the same time reducing to a minimum the liability to error.

General Proposition.—Let $P_0P_1P_2P_3P_4P_5$, Figs. 1 and 2, be any polygonal figures and OX, OY any two lines at right angles to one another, and let the distances $a_1a_2a_3$.... represent the horizontal distances of the points $P_1P_2P_3$.... from the vertical lines OY, which in the examples given coincide with the sides P_0P_5.

Let $h_0h_1h_2h_3$....be the vertical distances of the points $P_0P_1P_2P_3$....from the lines OX giving the + sign to the distances below, and the — sign to those distances above

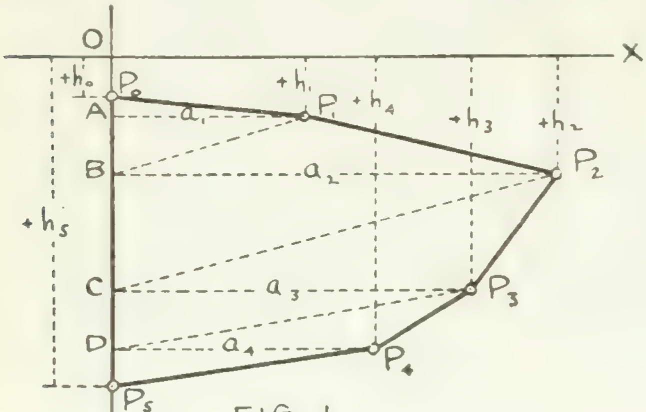

FIG. 1

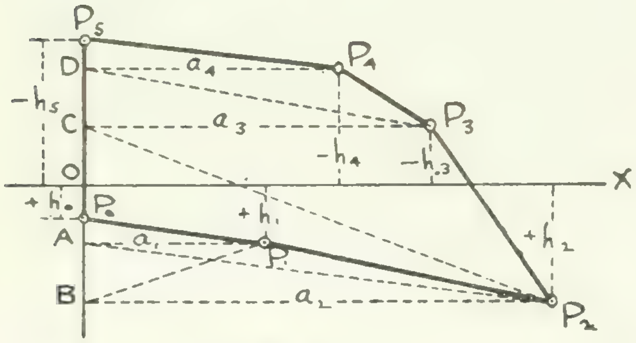

FIG. 2

OX. Then, the areas of the polygons $P_0P_1P_2P_3P_4P_5$ will be given by taking one-half of the algebraic sum of the products found by multiplying consecutively each horizontal distance $a_1a_2a_3$....by the algebraic difference between the ordinates of the points coming immediately after and before such horizontal distance: that is area of the polygon $P_0P_1P_2P_3P_4P_5$ for Fig. 1 will be

$$\tfrac{1}{2}\left[a_1(h_2—h_0) + a_2(h_3—h_1) + a_3(h_4—h_2) + a_4(h_5—h_3)\right]$$

and for Fig. 2

$$\tfrac{1}{2}\left[a_1(h_2—h_0) + a_2(—h_3—h_1) + a_3(—h_4—h_2) + a_4(—h_5 + h_3)\right]$$
$$\text{or } \tfrac{1}{2}\left[a_1(h_2—h_0) — a_2(h_3 + h_1) — a_3(h_4 + h_2) — a_4(h_5—h_3)\right]$$

The proof of the foregoing is easily seen, for drawing the horizontal dotted lines AP_1, BP_2, CP_3, DP_4 and the diagonal dotted lines BP_1, CP_2, DP_3, then for Fig. 1:

$\tfrac{1}{2}a_1(h_2—h_0) = \tfrac{1}{2}a_1BP_0 = \tfrac{1}{2}a_1(BA + AP_0) = \tfrac{1}{2}a_1BA + \tfrac{1}{2}a_1AP_0 = \text{area } BP_0P_1$;

$\tfrac{1}{2}a_2(h_3—h_1) = \tfrac{1}{2}a_2CA = \tfrac{1}{2}a_2(CB + BA) = \tfrac{1}{2}a_2CB + \tfrac{1}{2}a_2BA = \text{area } CBP_1P_2$;

$\tfrac{1}{2}a_3(h_4—h_2) = \tfrac{1}{2}a_3DB = \tfrac{1}{2}a_3(DC + CB) = \tfrac{1}{2}a_3DC + \tfrac{1}{2}a_3CB = \text{area } DCP_2P_3$;

$\tfrac{1}{2}a_4(h_5—h_3) = \tfrac{1}{2}a_4P_5C = \tfrac{1}{2}a_4(P_5D + DC) = \tfrac{1}{2}a_4P_5D + \tfrac{1}{2}a_4DC = \text{area } P_5DP_3P_4$ and the sum of these equals the whole area $P_0P_1P_2P_3P_4P_5$.

For Fig. 2 the proof is similar, for using the minus signs for the ordinates (corresponding to a fill or embankment) then

$\tfrac{1}{2}a_1(h_2 — h_0) = \tfrac{1}{2}a_1BP_0 = \tfrac{1}{2}a_1(BA + AP_0) = \tfrac{1}{2}a_1BA + \tfrac{1}{2}a_1AP_0 = + \text{area } AP_0P_1P_2$;

$— \tfrac{1}{2}a_2(h_3 + h_1) = — \tfrac{1}{2}a_2(CA) = — \tfrac{1}{2}a_2(CB—BA) = — \tfrac{1}{2}a_2CB + \tfrac{1}{2}a_2BA = — \text{area } ACP_2$.

$— \tfrac{1}{2}a_3(h_4 + h_2) = — \tfrac{1}{2}a_3BD = — \tfrac{1}{2}a_3(BC + CD) = — \tfrac{1}{2}a_3BC — \tfrac{1}{2}a_3CD = — \text{area } CP_2P_3D$;

$— \tfrac{1}{2}a_4(h_5 — h_3) = — \tfrac{1}{2}a_4CP_5 = — \tfrac{1}{2}a_4(CD + DP_5) = — \tfrac{1}{2}a_4CD — \tfrac{1}{2}a_4DP_5 = — \text{area } DP_3P_4P_5$,

and the algebraic sum equals the whole $P_0P_1P_2P_3P_4P_5$.

To adopt the above conclusions to field work so as to obtain direct from the level notes the areas of the cross-sections as taken:—

The horizontal line OX corresponds to the height of instrument and the line OY to a vertical line at centre.

The ordinates $h_0h_1h_2h_3$....are the rod readings taken at various points on the section and the horizontal distances $a_1a_2a_3$....the corresponding distances right or left of the C.L.

In the field book these are best noted in the form of a fraction, as shown on the sample page, the numerator being the rod reading, the denominator the corresponding distance:

The areas to the right and left of the centre line are calculated (as they are so taken in the field) separately and their sum gives the total area of the section.

The horizontal distances to the left could of course be given the minus sign and exactly the same final result would be obtained, but in practice it is simpler to imagine the left half section as being drawn on the transparent left page of a book, so that when this page is turned over the left half section would be superimposed upon the right on the right-hand page below, the centre line being represented by the line where the pages join. Thus all the horizontal distances, whether to right or left, can be given the plus sign. Taking the example at the head of the sample page, this section, if plotted, would appear as under.

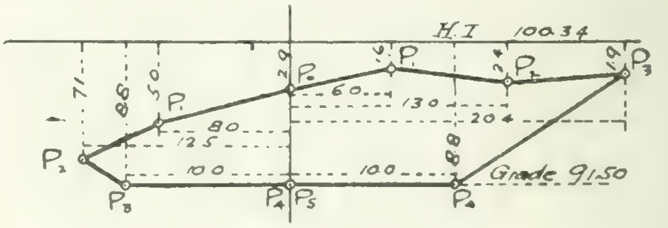

FIG 3

By the formula

area right $= \tfrac{1}{2}[\,6.0(2.4—2.9) + 13.0(1.9—1.6) +$
$\quad + 20.4(8.8—2.4) + 10.0(8.8—1.9\,]$
$\quad = \tfrac{1}{2}[—6.0,0.5 + 13.0,0.3 + 20.4,6.4$
$\quad + 10.0,6.9)$ .... = 100.23

area left $= \tfrac{1}{2}[\,8.0(7.1—2.9) + 12.5(8.8—5.0) +$
$\quad 10.0(8.8—7.1)\,]$
$\quad = \tfrac{1}{2}(8.0,4.2 + 12.5,3.8 + 10.0,1.7)$.... = 49.05

∴ Total end area 149.28

*Copyrighted, 1914, by the Author.

In working out these areas in the field book the rod readings or ordinates can usually be subtracted mentally and their difference at once jotted down (with the proper sign + or — affixed), as shown on the marginal page.

Should it be found impossible to complete the section with a single height of instrument, proceed as follows: Suppose a section on side hill.

Then, if there be but one or two sections requiring a change in the height of instrument, it would only be necessary after setting up, to find on the upper side the

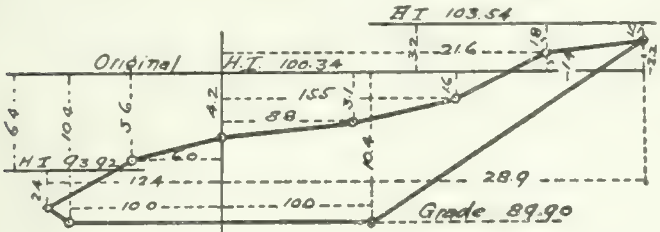

FIG. 4

difference 3.2 between 103.54 the new H.I. and 100.34 the original height, for then the rod readings as taken, subtracted from 3.2, would give the proper readings —1.4 and —2.2 referred to the original H.I.

On the lower or left-hand side of the section the new H.I. 93.92 being lower than 100.34, the original height, their difference 6.4 must be added to 2.4, the rod reading as taken, giving for this left side referred to the original H.I. a reading of 8.8.

If, however, there are a number of consecutive sections requiring various changes as above, it would be better perhaps to enter on another page of the level book, under their respective H.I., the rod readings as taken, and then on the marginal page before using such for calculating the end areas reduce them as shown above to the original H.I. by adding or subtracting the constant difference.

The original sections could then be completed by bringing back these corrected readings and the section for such a cross-section as that illustrated above would appear in the level book as shown in Table I.

TABLE I.

Station		C. or F.	B.S.	H.I.		F.S.	Elevation	Grade
				100.34				
	R	+12.[illegible]		[illegible] / 8.8	1.[illegible] / 15.5	See page	[illegible] / 21.[illegible]	[—2.2 / 28.9]
40		+ 6.2	4.2 / [illegible]					89.90
	L	+ 1.[illegible]			[illegible].6 / 6.0	See page.	[[illegible] / 12.4]	

The resulting end area would then be as already shown:

area R = ½ [8.8(1.6—4.2) + 15.5(—1.4—3.1) + 21.6(—2.2—1.6) + 28.9(10.4 + 1.4) + 10.0(10.4 + 2.2)]
= ½ [—8.8,2.6 — 15.5,4.5 — 21.6,3.8 + 28.9,11.8 + 10.0,12.6] .... = 146.15

area L = ½ [6.0(8.8 — 4.2) + 12.4(10.4 — 5.6) + 10.0(10.4—8.8)]
= ½ [6.0,4.6 + 12.4,4.8 + 10.0,1.6] .... = 51.56

∴ Total end area 197.71

TABLE II.

Station		C. or F.	B.S.	H.I.		F.S.	Elevation	Grade	H.I. to Grade	Calculations, Remarks	End Areas Exc'v'n	End Areas Emb'km't
				100.34						Road bed 20 ft. Exc [illegible] ft. Bank		
	R	+6.9		[illegible] / [illegible]	[illegible] / [illegible]	[[illegible] / 20.4]				$\frac{-6.0,0.5+13.0,0.3+20.4,6.4+10.0,6.9}{2}$		
41		—5.9	2.9 / 0					91.50	+8.8		149.3	
	L	—1.7		[illegible] / 8.0		[[illegible] / [illegible]]				$\frac{+8.0,4.2+12.5,3.8+10.0,1.7}{2}$		
	R	+3.7		[illegible] / [illegible]		[[illegible] / [illegible]]				$\frac{[illegible]}{2}$		
41+40		+2.9	0.1 / 0					91.30	+9.0		65.2	
	L	+0.7		[illegible] / 6.0		[[illegible] / [illegible]]				$\frac{+6.0,2.2+11.0,2.3+10.0,0.7}{2}$		
41+62		0.0		Grade				91.19			0.0	0.0
	R	[illegible]				[[illegible] / [illegible]]				$\frac{[illegible]}{2}$		
42		—[illegible]	12.1 / 0					91.00	+9.3			73.2
	L	—5.4		14 / 9.0		[[illegible] / 16.1]				$\frac{+9.0,2.6-16.1,5.0-8.0,5.4}{2}$		
T.P.			[illegible]	[illegible]		12.06	88.28			On rock 40 ft. Right of 42		
	R	[illegible]		[illegible] / [illegible]		[[illegible] / [illegible]]				$\frac{-9.0,1.6-12.5,4.0-8.0,3.0}{2}$		
42+60		—4.6	[illegible] / 0					90.70	—1.6			127.8
	L	—6.5		[illegible] / 5.[illegible]	4.0 / [illegible]	[4.0 / [illegible]]				$\frac{+5.0,1.9+10.0,1.8-17.7,6.5-8.0,6.5}{2}$		

Table II. is a sample showing manner of keeping the field notes and the method of calculating the end areas direct from these notes as taken.

The section shown in Table III. is on side hill, embankment to the left, excavation to the right, the grade point being as shown 2.5 feet to the right. This must be taken into account in making the calculations so as to keep the excavation and embankment areas separate from one another.

TABLE III.

Station	C. or F.	B.S.	H.I.	F.S.	Elevation	Grade
			89.12			
T.P.		9.16	97.52	0.76	88.36	
			Grade			
R	+4.0		$\frac{7.3}{2.5}$ $\frac{4.2}{6.5}$	$\left[\frac{3.3}{16.0}\right]$		
43+50	0.4	$\frac{7.7}{0}$				90.25
L	−2.2		$\frac{8.1}{6.4}$ $\left[\frac{9.5}{11.3}\right]$			

Thus, excavation area to the right is given by

½ [2.5(4.2—7.3) + 0.5(3.3—7.3) + 16.0(7.3—4.2) + 10.0(7.3—3.3)]

= ½ [—2.5,3.1—6.5,4.0 + 16.0,3.1 + 10.0,4.0] = + 27.9

There would then be to the right in embankment the small area given by 2.5(7.3—7.7)½ = —0.5 and this would have to be added to the embankment area to the left given of course by

½ [+6.4,1.8—11.3,0.8—8.0,2.2] = —7.6 that is a total area in embankment for the section of — 8.1.

It might, however, be considered less confusing in such cases to consider the vertical line as being placed at the grade point instead of at the centre of the section and then all the area to the right of this point would be in excavation and all to the left in embankment.

This would simply mean that in applying the method all horizontal distances taken to the right would be reduced by 2.5 feet and all distances to the left increased by the same amount, that is, area right would

= ½ [4.0(3.3—7.3) + 13.5(7.3—4.2) + 7.5(7.3—3.3)]

= ½ [— 4.0,4.0 + 13.5,3.1 + 7.5,4.0] = in excavation 27.9 as before, and area left would

= ½ [2.5(8.1 — 7.3) + 8.9(9.5 — 7.7) + 13.8(7.3 — 8.1) + 10.5(7.3—9.5)]

= ½ [+ 2.5,0.8 + 8.9,1.8—13.8,0.8—10.5,2.2] equal as before to a total area in embankment of 8.1.

MONTREAL WATER AND POWER COMPANY

The annual report of the Montreal Water and Power Company for the year ending April 30th, 1914, shows a gross revenue of $[illegible], an increase of seventeen per cent. over the previous year. The net operating profit, after paying all expenses, maintenance and bond obligations, was $208,000.

The first half of the new reservoir will be available for use by next September, and the remainder will be ready in a few months thereafter. Mr. Edwin Hanson, the president, stated that the filtration plant continues to be operated in a most satisfactory manner, and that the report of the company's experts indicates that it performs its work with great efficiency. It is intended to increase the capacity of the filtration plant as soon as possible.

A new transformer house has been erected at the main pumping station. It is intended to duplicate the electrically-driven pumps at the Clark Avenue station, and to install a new and large force main from the lower pumping station to the northern territory, eventually communicating with the reservoir in Outremont.

CONCRETE ROAD MAINTENANCE AND COSTS.

At the National Conference on Concrete Road Building, held in Chicago in February last, one of the committee reports dealt with the method and cost of repairing and maintaining concrete roads. This committee reported as follows through its chairman, Edw. N. Hines.

Maintenance work in Wayne County consists in filling the open expansion joint on the roads first built before the development and use of the armor joint, and in the filling with a mastic such longitudinal and transverse cracks as have developed.

A crew consisting of seven men and a team, provided with a tar kettle, is utilized for the work. The foreman is paid $5 a day, the team and driver $5, the "tar man" $3, two laborers $2.50 each and two others $2.25 each. The tools used consist of two wire bristle brooms, a wheelbarrow, a couple of shovels and a tar bucket with a round spout. Tarvia X is now used exclusively. A lighter grade was first tried out, but did not give such permanent results as the heavier grade. Two men are utilized to sweep all cracks clean with the wire brooms, after which the man with the tar kettle fills the cracks with the tar, which is heated to about 225° F. An excess of tar is poured in so that it extends an inch or so beyond the edge of the crack. It is then allowed to stand in the crack for a few minutes to prevent it from "bubbling" out in case the sand is wet. The sand, which should be dry and coarse, is spread with a shovel over the crack and into the tar, and the whole is left for traffic to iron out. The excess tar and sand is worn away rapidly, leaving a smooth, even surface, in passing over which no jolt is apparent.

The work is preferably done on hot, dry days. It has been suggested that the better time to handle this work would be in the late fall when the cracks would be open the widest due to contraction, but the results we have secured in the summer months have been so satisfactory that we have not tried out the latter plan. The small pit holes which are due simply to some foreign substance like clay, wood or some fragment of inferior rock which might chance to be a part of the aggregate, are treated in the same manner. As to the cost of this method, the report contains figures covering 10 pieces of road aggregating 10 miles, the cost of repairs for which, including tar, labor and sand, amounted to $1,300.50 from October, 1912, to October, 1913. Adding a percentage to cover engineering, inspecting, depreciation of machinery and building and other expenses, a total of $1,450 was obtained. The greater part of this mileage was treated for the first time.

The report dealt also with treating the entire surface of a road where the concrete from any cause had not stood the wear. Several pieces of road had not been built up to the standard of the balance of the construction and required surfacing. Others were rough, having been laid in cold weather and opened for traffic before the concrete had thoroughly hardened. The method of repairing one of these is worth noting. The road was first swept by a street sweeper, which was followed by men with wire brooms. About ½ gal. of bitumen to the square yard was used, and the whole covered with coarse sand and rolled with a 10-ton roller. This repair was made early in the summer and was not touched in any manner for a period of two years. By this time it had scaled off in spots quite badly, and was gone over again in the summer of 1913, using Tarvia X and a washed roofing gravel about ¼ in. in size.

WIND LOADS ON BUILDINGS.

THE determination of the distribution of wind loads on buildings has been a subject of a series of tests carried out by Prof. A. W. Smith, and concerning which several articles have been published by him during the past two years. He first obtained data on structures without floors between ground and roof—mill-buildings. The results obtained from these tests indicated that the common assumption in regard to wind loads did not come very near to the actual conditions. The summation of his results in this direction were presented in a paper before the Western Society of Engineers in October, 1912. Since that time Mr. Smith has extended his researches to include larger structures, such as train-sheds and drill halls, the results of which tests were presented several months ago to the same society and appeared in its Journal for April, 1914. From it the following points are reproduced:—

As a model a roof of semi-circular section, 6 ft. span and 10 ft. long, was constructed and covered with tin. This roof was mounted on walls 5 ft. high, made of 2 x 6-in. lumber, tongued and grooved. After each set of observations, the roof was lifted and 6 in. of the walls taken off. The use of tongued and grooved stuff made the walls comparatively tight, and also made them somewhat stiff when an end or side was omitted in the course of the tests. At a middle section of the building, holes were bored about 1 ft. apart in the walls and roof, the row extending from ground to ground. These holes were about ½ in. in diameter, and in the roof a short nozzle was soldered on the inside. A series of holes at various levels were also carried completely around the house.

The author describes in detail the pressure-recording instruments and the method of taking the observations, as well as the method of calibrating pilot tubes.

After the readings were taken the pressure or suction inside the house was standardized, and the result was reduced, first to pds. per sq. ft. and then to that for a velocity of 10 mi. per hr. The pressure or suction inside the house was found to be variable, partly because, in a somewhat gusty wind, the pressure condition in the house was found to lag behind the velocity changes outside, and also because small changes in the direction of the wind caused great changes in the conditions of exposure of the various leaks, which were not, of course, symmetrical around the house.

Observations were taken while the house was thoroughly caulked, so that the conditions were nearly ideal. Readings were also made on the model with different sides and ends omitted, as well as with portions of the walls removed. The paper included diagrams of measurements taken at the various observations with the model under usual different conditions.

Mr. Smith found that the forces on the building with one side open, while greater than for one of the same height with the side closed, did not exceed the proposed units. With the wind in the other direction, the pressure

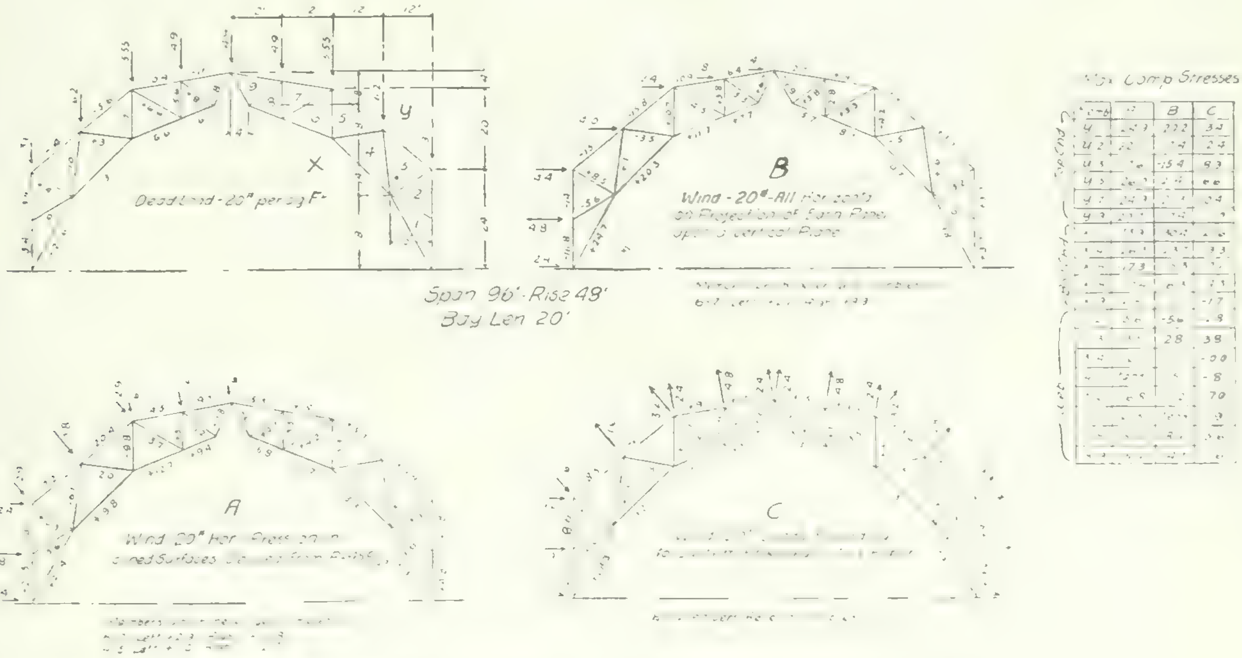

Fig. 1.—Comparison of Stresses in Arch from Different Loadings.

on the closed wall would be increased by a rarefaction inside the house, and the suctions over the roof would be diminished. Observations on the model with both sides removed show that the stresses for this case are less in amount, and nearly the same in distribution as for the closed house. A comparison of the stresses in a very simple two-hinged arch from three systems of wind-loading is shown in Fig. 1. It appears that if the wind loads are as shown by the test described, not only are the stresses assumed to be much too large in most cases, but in two cases they gave tension only in numbers which should be designed for compression. This truss is of exaggerated depth, and in a large truss of ordinary depth the discrepancies would be greater. Such arches are now made entirely of compression sections in most cases, but it would be better to adopt a loading system which makes it impossible to do otherwise. In Fig. 2 are shown the same comparison for a mill building bent. As in the arch, all members received compression from the proposed loadings, while by the common method three of these members would be designed for tension only.

Another experimenter, Mr. A. See, recently read a paper before the Industrial Society of Northern France, "The Wind Pressure on Roofs," relating to experiments

in connection with aeronautics which had raised a good deal of doubt as to the validity of the officially adopted formula for wind pressure against roofs and walls. Abstracts from his paper appeared in the Journal of the American Society of Mechanical Engineers for June, 1914. The results are interesting when considered in connection with the above, and are further abstracted herewith:—

It is usually assumed that the wind pressure on a surface with a plane normal to the direction of the wind is equal to the product of the area of the surface by the square of velocity, multiplied by the co-efficient 0.14.

In the case of a roof it is assumed that the wind moves downwards at an angle of 10 deg. and strikes the roof at an angle $a + 10$ deg., where a is the angle of the roof with the horizon. Under these conditions the pressure is obtained by multiplying the preceding equation by $\sin^2 (a+10)$. This official formula is, however, entirely antiquated and its lack of accuracy is obvious now that the coefficient of resistance of the air is known to be not 0.14, but 0.08. The hypothesis of the wind descending at an angle of 10 deg. is purely arbitrary. The law of sine square has been shown not to agree with experimental data, and finally the formula does not take into consideration the shape and location of the roof.

Experiments have been made recently at the Engineering Aeronautical Battalion of the Italian Army with models of two types of semi-lozenge shaped hangars (Fig. 3, A and B), where the pressure curve and the magnitudes of the pressures, at various points of the profile, are indicated. One sees at once that the pressure curve has nothing to do with either the sine square or simple sine law, or, indeed, with any law based on the angle of incidence. The wind pressures along the frontal surface of the structure rapidly diminish as the curve inflects, and become zero some time before the tip of the lozenge is reached; moreover, they become negative all along the rear surface, a fact which is not shown by the formula. There is, therefore, quite an important partial vacuum, independent of the curvature of the structure, and it appears that the wind pressure on each element depends not so much on the angle of incidence at that point as on the location of that particular element with respect to the rest of the structure.

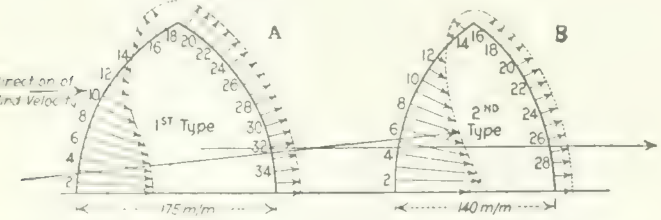

Fig. 3.—Distribution of Wind Stresses on Buildings.

When, however, one comes to the consideration of the question as to which formula would be more acceptable than the old official formula, one finds that while this official formula is incorrect, any other formula which might be derived at the present time would be just as likely to be based on arbitrary assumptions and involve coefficients of doubtful value. Whether the new formula would give better results is somewhat doubtful, while it is a fact that structures built in accordance with the old formula proved to be quite stable. The author, therefore, rather curiously arrives at the conclusion that while the old formula is admittedly incorrect it should still be followed, at least until an absolutely good new formula can be derived.

PROGRESS ON DRY DOCK AT FREDERICTON, NEW BRUNSWICK.

Norton, Griffiths & Co., Limited (Canada), engineers and public works contractors, are building a dry dock of considerable magnitude for the Dominion Government at Fredericton, N.B. The dry dock when completed will be 900 ft. long and 100 ft. in width. Up to the present time about six acres of land in the vicinity of the dock have been reclaimed and about nine acres of hilly ground on the site of a proposed ship-repairing plant to be constructed in connection with the dock, has been cleared to the level of the coping of the dock.

Excavation below coping level is in progress, a total quantity of rock and over-burden of approximately 410,000 cu. yds. having been removed to date.

COMPLETION OF TRACK LAYING ON THE GRAND TRUNK PACIFIC RAILWAY.

THE accompanying photographs are illustrative of the enthusiastic manner in which the last mile of the Grand Trunk Pacific Railway was furnished with steel. As the track-laying outfits from east and west approached each other it was decided to have a race for the finish. The west outfit reached the west end of Mile 111, Willow River, about noon of April 6th, and waited there until 11.30 a.m. of the 7th, when the outfit was ready to start from the other end of the mile. The two track-laying gangs then started simultaneously in a race to reach the stake which had been driven at the middle of the distance. The 0.4 of 1 per cent. grade was in favor of the east crew, but it was not expected that this would make any material difference in the speed of such work. Further, the machine from the east was housed in, but with this exception the two outfits were about the same, both being a modification of the Roberts track-laying machine, fitted with an air-hoist instead of a winch for handling rails. The east machine, however, was using a winch, the air-hoist having gone out of commission.

The east gang, in charge of Phil. Egan, made the half-mile in 42 minutes, while the west crew, under Dan Dempsey, reached the stake in 64 minutes. The chief difference between the methods of the two outfits was that Dempsey's machine laid a rail, moved ahead, stopped to lay another, and so on, while Egan did not stop, but moved slowly ahead. By this latter method the tie-buckers were obliged to carry a tie a very short distance only as compared with the other. While one man could handle a tie, in the west gang two men were required to do it. This method was also responsible for the unnecessary loss of several minutes owing to the locomotive on two occasions progressing beyond the desired point and having to back up.

When the last rail was laid, Mr. Kelliher, chief engineer; Mr. Morley Donaldson, vice-president and general manager; Messrs. Brewer and Meehan, superintendents, and Messrs. Egan and Dempsey, superintendents of track-laying, each drove a spike into it. The ceremonies were then concluded by the presentation of gold watches to the two track-laying superintendents. The event was witnessed by 700 or 800 spectators.

Laying the Last Mile of Track on the Grand Trunk Pacific.

West End Machine Prepared for Race.

East End Machine Coming up to the Finish.

Bringing on the last Rail.

This maximum grade against east-bound traffic of 0.4 of 1 per cent. is a striking feature of the new line through the mountains. Against west-bound traffic there is a maximum grade of 0.5 of 1 per cent. with the exception of a single pusher grade of 1 per cent., 19½ miles in length. The Grand Trunk Pacific Railroad traverses prairie country for a distance of over 922 miles between Winnipeg and Edson, Alta. The elevation at these two points is 767 ft. and 2,984.3 ft. respectively, the difference being in the form of a gradual rise. Immediately west of Edson the line encounters the mountains and in the Yellowhead Pass, a further distance of 123 miles, it reaches an elevation of 3,723.11 ft. Then the elevation drops over 1,200 ft. in the next 45 miles including the 1 per cent. grade referred to above. From this point no grades exceed 0.4 of 1 per cent. in either direction as the line traverses the valleys of the Fraser, Bulkley and Skeena Rivers.

It has been announced that on July 1st, a regular train service will be in operation between Fort George and Edmonton and that the company is expected to extend this service to Prince Rupert by early fall. We are indebted to Mr. S. V. Ardagh, Residency 46, Engineering Department, Grand Trunk Pacific Railway, Fort Fraser, B.C., for the photographs reproduced herewith.

The government at Cape Town, South Africa, has decided to erect a new lighthouse at Cape Point. The old lighthouse, of 2,500 candlepower, has been in existence for half a century, and will be superseded by a most up-to-date dioptric flashlight of 500,000 candlepower. It will stand 300 feet above sea level, and will have a range of 24 miles. The estimated cost is £8,000.

WIRE AND CABLE PLANT OF THE NORTHERN ELECTRIC COMPANY, MONTREAL.

THE new wire and cable plant of the Northern Electric Company, Limited, now nearing completion in the city of Montreal, occupies an area of 178,000 sq. ft. (over four acres). The present plant having been found inadequate, expansion has necessitated the erection of this new structure, which, when completed, will be one of the largest in America for the exclusive manufacture of wires and cables. The E. G. M. Cape & Company, Limited, have the general contract for the building. The foundations for walls and columns are composed of plain and reinforced concrete. In the main building and some of the one-story portions the columns rest on Raymond concrete piles, of which 4,000 have been driven, with an average length of 12 ft. On each group of piles rests a reinforced concrete cap, on which bases for the building columns are placed.

The 6,500 tons of structural steel required for the superstructure were supplied and erected by the Dominion Bridge Company. Bethlehem "H" columns girders and beams were used almost exclusively throughout.

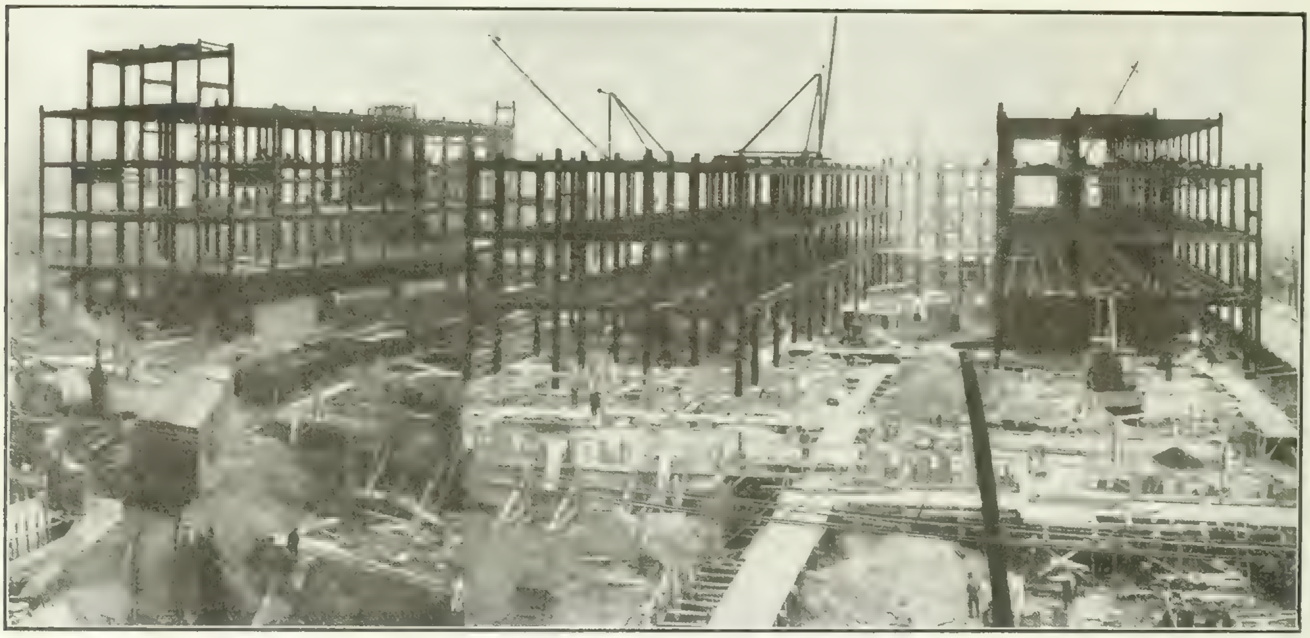
Fireproof construction has been used throughout the entire building. All interior columns are encased in 4¾ inches of hollow terra cotta, and beams in 2⅜ inches. The floors are composed of hollow terra cotta segmental arches with a span of 6 ft. 8 in., and are suitable for a live load of 288 lbs. on the second to seventh floors and 150 lbs. on the eighth floor. A stone concrete fill is poured over the arches, in which wooden sleepers are embedded, and the underflooring is nailed to these sleepers, and over this, the final maple flooring is laid at right angles. The National Fireproofing Company supplied all the fireproofing terra cotta, amounting to 11,000 tons.

The walls are built of Laprairie Plastic Brick, seven millions being used. All the lintels in the courts and on the street sides, together with the architectural ornaments and copings on the street sides, were supplied by the Atlantic Terra Cotta Company, of Tottenville.

The main buildings, shaped like the letter "E," have two main courts, which serve to provide ample lighting facilities for the 500,000 sq. ft. (over 12 acres) of floor space from the interior, as well as the exposed sides on the streets. These courts have sloping roofs of book tile, with large skylights. The G.T.R. and C.P.R. railway tracks run into one court, which has large platforms for shipping and receiving purposes. Each track is provided with a 150-ton Canadian Fairbanks-Morse Company track scale.

There are four travelling electric cranes, one 50-ton, one 20-ton, one 20-ton with 5-ton auxiliary hoist, and one 10-ton all made by the Case Crane Company. The 50-ton crane will be used for handling reels of armored cable, the 20-ton for the lead-covering department, the 20-ton with 5-ton auxiliary for the turbine room, and the 10-ton for the impregnating tank room. The two 20-ton cranes are arranged so that they can pass material to the 50-ton, which will convey it over the railway tracks, or vice versa.

Fire walls, with automatic steel fire-doors on both sides, divide the building into various sections. Each section has a fire and smoke-proof stair tower, with iron stairs at both ends, thus providing ample and safe means of exit in case of fire on any floor. The fire-doors for the whole building were supplied by the Architectural Bronze and Iron Works, and the iron stairs by John Watson & Son, Limited. All windows throughout the building have steel frames with wire glass. Pivoted sections of these windows can be opened with operating chains equipped with fusible links, thus making them self-closing in case of fire. The 95,000 sq. ft. of steel sash required for the factory was supplied by the Trussed Concrete Steel Company, and the casement sash for the offices by Henry Hope & Son, Limited.



New Plant in the Process of Erection: Steel Almost All in Place.

All drains and underground sprinkler mains are being installed by James Ballantyne. The sprinkler and fire hose systems above the first floor level are supplied by H. G. Vogel Company (Canada), Limited, and consist of 6,000 sprinkler heads and fire hose, located at convenient points in the building. These systems are supplied with water from the city mains, steamer con-

nections on the street, and a 1,500-gallon Worthington underwriter's fire pump, which is connected to a 100,000-gallon concrete reservoir and the canal.

Five 6,000 and one 15,000 lb. freight elevators, with a travel of 100 ft. and 25 ft. per minute, respectively, will be used to handle the transfer of material for manufacturing, and two high-speed passenger elevators, travelling at 350 ft. per minute, will be used to serve the general offices of the company, which are situated on the eighth floor of the building. They are being supplied by the Otis-Fensom Elevator Company. This floor has no columns, the roof being supported by steel trusses with large skylights. The absence of columns afford splendid facilities for the laying out of offices to suit the requirements.

A unique point in the design of the building is the storage space secured on the roof of one section by means of paving bricks. This roof is served by means of one of the 6,000 lb. freight elevators.

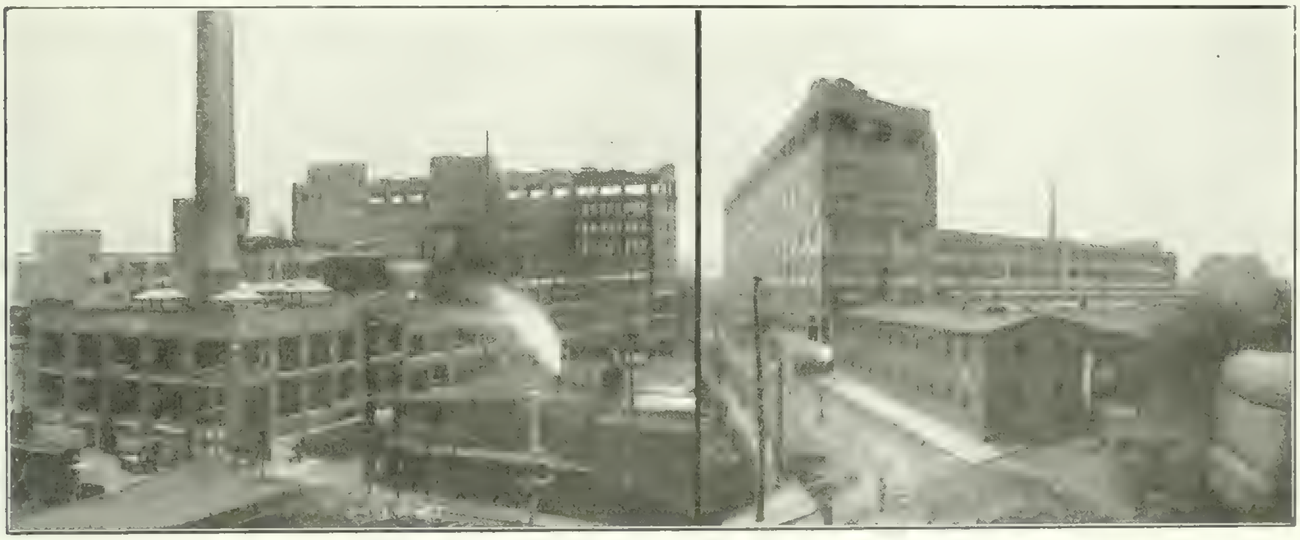
Large intake pipes from the canal supply the reservoir and the water used for condensing purposes. An automobile garage and a wagon court are so arranged that the material can be readily loaded for city delivery without having to cross the railroad tracks.

The building will be heated by a forced circulation hot water system. Exhaust steam from one of the main turbines will be passed through closed heaters. The water will be circulated by means of a 4,000-gallon Alberger single-stage volute pump, directly connected to an Alberger-Curtis steam turbine. The vapors and condensate from the exhaust steam will be carried from the heaters by means of an Edwards air-pump with a tail-pump. This makes a very flexible system to suit the changes in the outside temperature, as the vacuum can be increased in warm weather, thereby creating a lower temperature of the exhaust steam and decreasing the amount of steam required by the turbine as the vacuum increases. In extreme cold weather the turbine can exhaust into the heater at atmospheric pressure, and thus increase the quantity and temperature of the stream. When running two turbo-generator units in parallel, one turbine can run condensing, while the other exhausts into the heating system, and its load can be varied to suit the amount of steam required for heating purposes. The power plant equipment for this heating system is in duplicate, either one of the units being large enough to take care of the whole system. The enclosed heaters mentioned above were built by John McDougall Caledonian Iron Works, Limited.

The water required for the house service system and for manufacturing purposes will be pumped from the 42-in. intake pipe mentioned above by means of Deane motor-driven, single-acting, helical-geared triplex pumps, supplied by John McDougall Caledonian Iron Works Company, Limited.

The Canadian Ingersoll Rand Company are supplying two steam-driven air-compressors, which have a combined capacity of 1,200 cu. ft. per minute.

The power plant is of the most modern design. Coal can be stored in large quantities, and will be transferred to the storage bins over the front of the boiler by means of a Telpher car and clam-shell bucket. Ash-handling equipment takes the ashes directly from ash-shutes under the boilers and delivers them into ash-storage bins, which in turn deliver them into railroad cars or carts for disposal. Ashes can also be handled by means of small cars on an industrial railway running in the basement of the boiler-room. The Telpher car will raise the body of each of these cars off the truck, through a hatchway in the main boiler-room floor, and will carry them over to the ash-storage bin. This method of ash-handling will only be used when it is necessary to overhaul and repair the regular ash-handling equipment.



Two Views, from Different Directions, of the Buildings.

A 225-ft. chimney, built by the Alphons Chimney Construction Company, serves four B. & W. boilers, nominally rated at 650 horse-power, but which will be forced to deliver 1,000 horse-power when necessary. These boilers are fitted with B. & W. chain-grate stokers and superheaters. The exhaust steam and condensate from the heaters, turbines, condensers, and steam-driven auxiliaries are brought to a Warren & Webster feed-water heater, which is capable of raising 107,000 lbs. of water per hour to 210°. From this heater the water is returned to the boilers by means of two Weir boiler feed-pumps, each with a capacity of 6,000 Imperial gallons per hour. General Electric Company Curtis horizontal turbines form the motive power for the generators, and are placed on structural steel stands directly over the Alberger centrifair condensers, thus insuring a high vacuum. The condensers are located over two 42-in. pipes leading to the canal. From one of these pipes the water is drawn by a turbo-volute turbine-driven pump, and

after having passed through the condenser is discharged into the other pipe. Tunnels leading from the turbine and pump-room are used to run the power and lighting circuits, the flow and return pipes of the forced hot water heating system, the house service water lines, and the high-pressure steam lines for manufacturing purposes.

The turbine-room has been laid out for two 2,000 K.W. and two 1,000 K.W. turbo-generators, two 460 K.W. rotary converters and two 75 K.W. turbo-driven exciters. Of these, 1,000 K.W. and one 2,000 K.W. turbo-generators and two rotary converters will be installed now. The generators are 3-phase, 60-cycle, 440-volt, star-wound, with neutral connection brought out to the switchboard. The exciters are 125-volt, and generator voltage will be controlled by Tyrrill regulator.

Air for the ventilation of the generators will be taken from a duct in the foundations of the generators and forced through the windings and air passages by fans integral with rotors. Screens will be provided in the pent-house of this duct to exclude dust, etc.

The connected load will be approximately 550 h.p., d.c. at 115 volts, and 4,000 h.p. a.c. at 440 volts. For the supply of the former, two 460-K.V.A. rotary converters, with necessary transformers and starting switches, will be installed, the neutral being brought out from each transformer bank for the neutral of a 115/230 volt, 3-wire, d.c. system.

The switchboard for the control and distribution of this power will consist of a main board of 25 Blue Vermont marble panels on the turbine-room floor. On this board will be mounted the meters for measurements of outputs of generators and loads on the feeders; also the d.c. bus-bars, both for exciters and d.c. factory load, and control equipment for 25 solenoid operated feeder switches for a.c. distribution. These switches will be mounted on Monson slate panels on a mezzanine floor under the turbine-room floor. The a.c. 440-volt bus-bars and generator switches will also be located here.

Generator switches will be non-automatic, with bell-ringing attachment, and feeder switches automatic, as mentioned above. All feeders will leave the turbine-room in a tunnel, from which they will branch off to the various buildings in 3-in. fibre conduits. These fibre conduits will lead to cable-pits, from which risers of 3-in. conduit will be carried to distributing panels. All a.c. cables will be 3-conductor paper insulated, leaded, direct current cables being single-conductor, leaded. For lighting factory area, 4-light clusters, wired in series-parallel, will be used. As mentioned above, the neutral point of generator windings will be brought out. The lead sheath of the lighting feeder cables will be bonded to the neutral bus and lighting circuits will connect one wire to one of the three conductors, the other to the sheath, giving approximately 266 volts across two lamps in series. Lighting feeder cables will lead to distributing boxes on the third floor of each section, from which circuits will run to the panel boxes on the different floors. Power feeders will run to distributing boxes on the third and fifth floors, from which circuits will run to power loops on each floor.

All wiring except that in general offices will be open conduit. The general offices will have outlets for fans, dictographs, annunciator and telephones, all wiring concealed in conduit. A large number of 3-phase, 60-cycle motors will be used for direct-connected, belt and group drives. L. K. Comstock & Company have the contract for wiring the lighting and power circuits.

An artesian well is being drilled by Wallace Bell Company, Limited, and will be used for drinking water and for manufacturing purposes.

In addition to the fibre protection system, a regular watchman's service system will be installed, so that the building will be patrolled at all times outside of the regular working hours. For the convenience of watchmen and to avoid the use of oil lanterns in the plant, a certain number of electric lights will be kept burning all night to form a pilot system, so that in cases of emergency the workmen in the building can easily locate the fire apparatus and also the exits.

The following features in connection with the building are of interest:—

The total excavation amounts to some 50,000 cu. yds. Over 14,000 cu. yds. of concrete have been used for foundations. 1,500 carloads of building material have been received up to the present time. 100,000 sq. ft. of glazing has been used, and approximately 100,000 sq. ft. hot water radiation service will be required.

The work has been executed under the direct supervision of Mr. E. F. Sise, President of the Northern Electric Company, Limited; Mr. J. D. Hathaway, General Superintendent; Mr. J. S. Cameron, Plant Engineer, and Mr. W. J. Carmichael, Architect.

USE OF POWDERED FUEL.

Fuel economy and the intimately associated problem of smoke abatement are receiving much attention. Among the methods discussed none perhaps is of greater interest than the burning of powdered coal The experiments made in this direction are of especial value to all who are interested in the utilization of peat. The work done by Lieutenant Ekelund in Sweden, according to the Journal of the Canadian Peat Society, has already demonstrated that peat has very great possibilities when used in powdered form. Its composition and physical properties make it in some respects superior to coal for this purpose.

The requirements for best results in burning powdered coal are thus stated by an authority.

(1) Coal must be dried to contain not over 1 per cent. of moisture.

(2) It must be pulverized to a high degree of fineness.

(3) It must be projected into a chamber hot enough to cause instant ignition.

(4) It must be supplied with sufficient air for complete combustion.

The standard of fineness given by the same authority is:—90 per cent. through a 400 mesh screen; 2½ per cent. to 5 per cent. through a 200 mesh screen, and the balance through a 100 mesh screen.

The cost of preparation of coal is variously estimated at from 32½ to 36½ cents per ton, with power at 1½ cents per k.w. hr.

It must be kept in mind that there is present in powdered fuel a certain percentage of extremely fine material, depending on the character of the fuel, its moisture content, and method of pulverization. The character of the flame is materially influenced by this impalpable dust which gasifies instantaneously.

The physical structure of peat is such that a large percentage of very fine powder would be more easily obtainable than in the case of coal, thereby increasing the rapidity of combustion.

Another point in favor of peat powder is the usual high content of volatile matters in peat. There is much divergence of opinion as to the amount of volatile matter required in coal to render it suitable for burning as powdered fuel. The majority of writers seem to think that 30 per cent. of volatile matter is a prerequisite, but some report satisfactory conditions with but 20 per cent. The higher the volatile the larger amount of the combustible will be converted into gas by the mere application of heat, and the more rapid and perfect the combustion. Ontario peats examined contain as high as 60 to 70 per cent. volatile matter, and should produce a highly efficient powdered fuel.

As in the production of peat fuel generally the important question is the removal of the moisture at such cost as to render the fuel economic.

Coast to Coast

Fort William, Ont.—The plant of the National Tube Company at Fort William is completed, and the works have commenced operating.

Montreal, Que.—The Canadian Fire Underwriters' Association is urging the inspection by competent engineers of Montreal's system of fire protection.

Regina, Sask.—The provincial highways commission of Saskatchewan is proceeding with a program of road construction work of a more extensive character than that of the past season.

Weyburn, Sask.—Preparatory work in connection with the laying of steel on the G.T.P. Weyburn-Talmage branch began the first week in June, and it is anticipated that the department will have the metal laid into the city by June 15.

Edmonton, Alta—Edmonton has decided to construct a municipally-owned paving plant at a cost of $37,000. It is to be in operation within 30 days, and it is planned to lay a' least 100,000 square yards of pavement before the close of the 1914 season.

Winnipeg, Man.—While recently in Winnipeg, Mr. David McNicoll, vice-president of the Canadian Pacific Railway company, stated that the company would spend much money this and succeeding years on railroads in the Okanagan Valley, British Columbia.

Kingston, Ont.—A concrete bridge on stone foundation has been completed at Dog Lake, which has been built by the county and Palmerston township conjointly at a cost of $5,000. The bridge is 300 feet long, and has a central iron span 28 feet wide. It is reported as a very satisfactory piece of work.

Vancouver, B.C.—C.P.R. engineers and surveyors left Campbell River recently in two parties working on the preparation of surveys to carry the line of the Esquimalt and Nanaimo Railway northward along the shore of Vancouver Island. One survey party is working south of Campbell River, and one north, the later proceeding along the trail built by the government into the Salmon River Valley. It is stated that the intention of the C.P.R. is to build eventually to the north end of Vancouver Island.

Moose Jaw, Sask.—City Engineer Mackie has at present under investigation 11 gravel pits which have been offered to the city for purchase. The city intends acquiring a gravel pit with a view to using the gravel therefrom for macadamizing the principal residential streets throughout the city. The city engineer states in the course of an interim report to the works committee that, in his opinion, the cheapest method of securing good surfaces is by the use of some sort of macadam, such as gravel screened and graded; and by the treating of this, in order to yield a satisfactory surface, with some patent road material, such as "Rocmac."

York Township, York County, Ont.—At the recent meeting of the Central Ratepayers' Association of York township, a proposal was submitted by a representative of a United States firm of engineers, whereby the firm will construct a waterworks system in the township and guarantee a water supply to the residents at a fixed price per 1,000 cubic feet, the cost of construction to be borne entirely by the firm and the water to be brought a distance of 25 miles and supplied to all houses. If the ratepayers were to construct their own system, however, the company will undertake to supply the water. Further discussion of the scheme will be held at public meetings of the ratepayers before any decision is announced.

Victoria, B.C.—Mr. J. W. Stewart, president of the P.G.E. Railway company, has made a statement to the effect that the company's entire line is now under contract with the exception of about 34 miles. Grading is in progress along the whole right-of-way from Squamish to Fort George and will practically be finished this year. Also before the end of this year, it is intended to put in operation an accommodation train service between Squamish and Lillooet. Mr. Stewart announced further that, within a few weeks, development work will be started on the Coast terminals of the Pacific Great Eastern at Squamish. This will involve large expenditures for the improvement of the harbor and the laying out of the townsite.

Toronto, Ont.—Mr. C. R. Barnes, expert for the Ontario Railway Board, has recently presented to the Corporation Counsel a report upon the Toronto Street Railway. He finds that the seating capacity of Toronto street cars is inadequate, and recommends an increase of over 50 per cent. The present seating capacity of 29,069 during rush hours should be increased by 10,813, half of this number by the beginning of November next, and the rest a year from that date. Many of the cars in use are found to be out of date, and it is recommended that 37 single-truck cars and 71 closed trailers be replaced by new cars approved by the board by the first of November next. An additional 29 cars should be in service on new lines by the same date. In addition to this the platforms should be lengthened on 200 double-truck cars.

Calgary, Alta.—The latest estimate on the cost of the proposed concrete bridge at Ninth Street West across the Bow river at Calgary is $165,000, or $5,000 more than the figure given some time ago, and $105,000 more than the steel bridge that was voted for by the ratepayers some time ago. The by-law upon the subject has been prepared, and it was submitted to the City Council at the meeting held recently, but no action was taken, the proposal being referred to the Finance Committee for consideration. The figures, which have been revised by City Engineer Craig, provide $150,000 for the cost of the bridge and $15,000 for engineering and contingent account. The bridge which the ratepayers voted for when the three bridge by-laws were before the people some time ago, was a steel bridge to go alongside of the present steel Louise bridge. This bridge would cost $60,000.

Victoria, B.C.—Work is progressing in three tunnel shafts in connection with the Northwest sewer at Victoria. The first two are in the portion open in Esquimalt, the third at Sunnyside abutting on the Gorge waters. Preparations are being made to start a fourth shaft at Smith Street; while a considerable amount of work has been accomplished on the Cecilia road tank. At the first shaft, near the sea at McLoughlin point, 160 feet have been pierced to the south and 180 feet to the north side of the tunnel. The excavation from the outfall to No. 1 shaft has been opened for about 2,000 feet, and steps have also been taken to open a drift towards that shaft in order to increase the opportunities to advance this section. At No. 2 shaft about 160 feet north and 180 feet south have been worked, and the junction with the section of tunnel being worked from No. 1 shaft, should be effected in August. From No. 2 shaft the trench on Smith street has been opened about 500 feet, while on Gore, Head and Dunsmuir streets in trench excavation about 1,000 feet have been opened. At Dunsmuir street, the present terminus of the open excavation, a tunnel will be commenced continuing at a considerable depth under that street. It is possible that another shaft will be sunk at the other end to secure a face to work at the tunnel from that section. At the Sunnyside tunnel, No. 3, a drift of about 120 feet has been made. At the Cecilia road tank, which is rendered necessary by the levels of the land to be drained north of the Gorge, the steel is in place, and the concrete floor laid; and the concrete will be poured for the walls in the course of the next few days.

PERSONAL.

R. W. BROCK, Deputy Minister of Mines, Canada, will, as announced, spend a portion of the summer on a geological study of the Bulkley Valley, B.C.

WM. C. ROWSE, B.Sc., M.E., has been appointed professor of mechanical engineering at the University of Manitoba. Prof. Rowse is a graduate of Purdue University.

C. F. J. GALLOWAY, M.E., of the British Columbia Department of Mines, is investigating the mineral-bearing areas along the route of the Grand Trunk Pacific Railway, working east from Hazelton.

A. B. GARROW, for several years in the main drainage department, City of Toronto, and now in the employ of the Toronto Harbor Commission, is in charge of the redesigning of the sewer outlets along the city's water front, found necessary in connection with the harbor development scheme of Toronto.

ARCH. CURRIE, City Engineer of Ottawa, has returned from Atlantic City, where he has been recovering from a lengthy period of illness. Mr. Currie is still unable to assume complete charge of his duties, owing to the condition of his health, and will, therefore, act merely in an advisory capacity on the more important matters until his health has been regained.

G. A. McCARTHY has been appointed to succeed C. W. Power (see *The Canadian Engineer*, June 11, 1914, p. 875), as railway and bridge engineer for the City of Toronto, and will assume his duties on July 1. Mr. McCarthy, a graduate of McGill University, Montreal, has had extensive experience in railway work, having been with the International Railway for seven years, followed by a position with the Algoma Central as assistant chief engineer, and from 1905 to 1909 with the Temiskaming and Northern Ontario Railway as chief engineer. Since then he has been with the firm of Smith, Kerry and Chase, which, after the decease of Mr. Cecil B. Smith, became Kerry and Chace, Limited. In addition, Mr. McCarthy has had sound experience on general engineering work, and will be a valuable asset to the works department of Toronto.

OBITUARY.

Notification has been received of the deaths of Robt. and E. S. Morrison in the Fraser river, B.C., at a point about 140 miles north of Kamloops. The latter was resident engineer of construction for the Canadian Northern Railway at Blue river. His brother was also engaged in railway work for the same company as timekeeper.

The death occurred in England of Prof. Robert Crawford, prominent in engineering both there and in Canada, and for a time professor of engineering at McGill University.

Early last week death came with unusual suddenness to Mr. Robt. H. Skelton, who for 6 years has been manager of the Ontario Sewer Pipe Company, Limited, Mimico, Ont. Mr. Skelton was in his 54th year.

The death occurred last week of Mr. William Armstrong, of Toronto, who was connected with early railroad work on the Grand Trunk and old Northern Railways. Prior to coming to Canada in [illegible] he was on the staff of the Midland and other railways in Great Britain.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS.

The 6th semi-annual meeting of the American Institute of Chemical Engineers is being held this week at Troy, N.Y., June 17th to 20th inclusive. Technical sessions are being held at which the following papers are being read according to the programme:—

"The Application of Physical Chemistry to Industrial Processes." By W. F. Rittman.

"Studies on Filtration." By J. W. Bain and A. E. Wigle.

"Scrubber for Vacuum Apparatus for Laboratories." By Chas. Baskerville.

On Wednesday night, Professor M. C. Whitaker will present his presidential address. This will be followed by an illustrated lecture by Dr. Wm. P. Mason on the Saratoga septic tanks.

On Friday morning the following papers will be presented:—

"Shoddy and Carbonized Waste." By L. J. Matos.

"The Present Patent Situation." By M. Toch.

"Bleaching Cotton Fibre." By J. C. Hebden.

"Ozone in Ventilation." By J. C. Olsen and Wm. H. Ulrich.

The programme for the Friday night session comprises the following two papers:—

"Development of Rotary Furnaces." By R. K. Meade.

"A Combination Water Softener and Storage Tank." By L. M. Booth.

Professor M. C. Whitaker is president and Dr. John C. Olsen, Polytechnic Institute, Brooklyn, N.Y., is the secretary of the Institute.

CANADIAN MANUFACTURERS' ASSOCIATION.

The Canadian Manufacturers' Association held its annual meeting in Montreal, June 9th, 10th and 11th.

COMING MEETINGS.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30th to July 4th, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—Summer convention to be held at Brighton Beach, N.Y., July 3rd and 4th, 1914. Secretary, J. R. Wemlinger, 11 Broadway, New York.

UNION OF CANADIAN MUNICIPALITIES.—Annual Convention to be held in Sherbrooke, Que., August 3rd, 4th and 5th, 1914. Hon. Secretary, W. D. Lighthall, Westmount, Que. Assistant-Secretary, G. S. Wilson, 402 Coristine Building, Montreal.

AMERICAN PEAT SOCIETY.—Eight Annual Meeting will be held in Duluth, Minn., on August 20th, 21st and 22nd, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

CANADIAN FORESTRY ASSOCIATION.—Annual Convention to be held in Halifax, N.S., September 1st to 4th, 1914. Secretary, James Lawler, Journal Building, Ottawa.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chausse, 5 Beaver Hall Square, Montreal.

CONVENTION OF THE AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—To be held in Boston, Mass., on October 6th, 7th, 8th and 9th, 1914. C. C. Brown, Indianapolis, Ind., Secretary.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9th to 13th, 1914. I. S. Pennybacker, Executive Secretary, and Chas. P. Light, Business Manager, Colorado Building, Washington, D.C.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21913—May 29—Directing that C.P.R. install gates at crossing of Hurontario St. in Tp. Toronto, to be operated by day and night watchmen; and file detail plans of said gates for approval of Engineer of Board within 30 days from date of this Order, 20 per cent. of cost of installing gates be paid out of "The Ry. Grade-Crossing Fund," and remainder by Ry. Company, 20 per cent. of cost of maintaining said gates be borne and paid by County of Peel, including wages of gatemen; remainder paid by Ry. Co. Gates be erected and in operation by July 1st, 1914.

21914—June 1—Directing that crossing of C.P.R. by St. John Ry. on Main St., city of St. John, N.B., be protected by half interlocking plant; derails be placed on St. John Ry. and home signals on C.P.R.; derails to be interlocked with said signals. Normal position of signals be at "proceed" for C.P.R. and "stop" for St. John Ry. Co.; in movement of trains C.P.R. to have priority. St. John Ry. Co. to bear and pay cost of installing, maintaining and operating half-interlocking plant.

21915—June 11—Authorizing C.P.R. to open for traffic second main line track between Agincourt, mileage 87.3, and Leaside Jct., mileage 95.6, Toronto Subdivision, Ontario Div., Ontario.

21916—June 1—Authorizing C.L.O. and W. Ry. (C.P.R.) to carry traffic over railway from Glen Tay to Agincourt, mileage 0 to 182.6, Ontario.

21917—June 1—Approving location Montreal and Southern Cos. Ry., from westerly boundary village of Granby, thence easterly upon and along Main Street, Drummond St., Irwin St. and St. Charles St., said village of Granby, subject to terms and conditions contained in said By-Law No. 192.

21918—June 1—Authorizing Nelson and Fort Sheppard Ry. Co., to construct spur into premises of The Benton Pole and Timber Co., five miles west of Erie, Lot 1237, West Kootenay Dist., B.C.

21919—June 1—Approving location Montreal and Southern Cos. Ry., from boundary line between parish St. Cesaire and parish St. Paul de Abbotsford, Co. Rouville, Que., to west boundary of town of Granby, mileage 35.05 to 45.61.

21920—June 1—Authorizing Montreal and Southern Cos. Ry., to construct across public highways between Lots 178 and 179, and between Lots 217 and 48-47, parish St. Paul de Abbotsford, Co. Rouville, Que.

21921—May 22—Directing that Dominion Atlantic Ry. fill in approaches to crossing of Grafton Road, Grafton, N.S., a distance of 300 ft. to south and 400 ft. to north; work be done at expense of Ry. Co. and maintained for period of 1 year from date of this Order.

21922—June 6—Directing that C.P.R. re-establish and maintain train service between Winnipeg and Gimli that existed prior to 1st June, 1914, until sittings of Board at Winnipeg, on Friday, June 26th, 1914, when those interested in matter shall be heard.

21923—May 29—Directing G.T.R. to construct extension of interchange track (between G.T.R. and Hamilton Radial Electric Ry. near Burlington, Ont.), so as to accommodate at least ten cars; work be completed within 60 days from date of this Order. Cost of work be borne and paid ½ by G.T.R. and ½ by Hamilton Radial Electric Ry. Co.

21924—May 28—Dismissing application Board of Trade of Sheho, Sask., for Order directing C.P.R. to remove station at that point from present location to town side of track.

21925—May 26—Dismissing application town of Gladstone, Man., for Order directing C.N.R. and C.P.R. to construct highway over respective lines of said railway Cos., at Dufferin St., in town of Gladstone.

21926—May 26—Refusing request of residents of village of Lac du Bonnet, Man., for Order requiring C.P.R. to build platform at point opposite village, and requiring local train of said Co. to stop at said platform at night and in morning.

21927—June 2—Certifying that correction of C.L.O. and W. Ry. (C.P.R.), plan to show division line between lands of W. A. Beare and Mrs. S. Beare on location indicated in red instead of on location indicated in green on plan dated May 15th, 1914, has been allowed.

21928—June 4—Authorizing C.P.R. to construct, at grade, its Lake Louise Branch Line across highways between mileage 0 and 3.55 of said Branch Line.

21929—June 4—Authorizing C.P.R. to operate its trains over bridge No. 30.5, Temiskaming Subdivision, Lake Superior Division.

21930—June 4—Amending Order No. 21706, dated April 21st, 1914, by striking out word "clearance," in two last lines of operative part of Order, and substituting word "distance."

21931—May 29—Directing that C.P.R. construct subway at crossing of Hurontario St., Tp. Toronto, Co. Peel, Ont.; subway to be 20 ft. wide and have 14 ft. clearance. Work be completed by September 1st, 1914. 20 per cent. cost of construction be paid out of "Ry. Grade-Crossing Fund," remainder as follows:—15 per cent. by Tp. Toronto, and 85 per cent. by Railway Company.

21932—June 1—Authorizing Bay of Quinte Ry. Co., to open for traffic diversion of its line in Lots 32, 33 and 34, Con. 8, Tp. Camden, Cos. Lennox and Addington, Ontario.

21933—June 4—Authorizing V.V. and E. Ry. and Nav. Co., to reconstruct bridges across C.P.R. at Grand Forks, B.C., subject to condition that should any additional tracks be built by C.P.R. at said point, V.V and E. Ry. and N. Co. bear and pay expense of making necessary changes to provide for same.

21934—June 2—Authorizing G.T.R. to construct siding into premises of Siemon Brothers, Limited, Park, Lot 1 and Park Lot 0, town of Wiarton, Ontario.

21935—May 26—Dismissing application Frank Yestran, village of Rosewood, Man., for Order requiring C.N.R. to stop its "Flyer" train at Dufresne, Man.

21936—June 5—Amending Order No. 21913, dated May 29th, 1914, by striking out word "Hurontario," where it occurs in recital and operative parts of Order, and substituting word "Dundas."

21937—May 29—Directing that G.T.P. Ry., file with Board, within 30 days from this date, plans showing location of Standard No. 1A Station with 60 ft. platform at point between Tofield and Deville, Mile Post 759, stock pen with necessary platform and loading chute, also spur to hold at least 4 freight cars; all to be completed before Sept. 1st, 1914. Also that wayfreight and passenger trains, other than through passenger trains, stop at said station.

21938—May 29—Authorizing city of Edmonton, Alta., to open Spruce Ave., across C.N.R. in Edmonton; and it is also authorized to construct its Municipal St. Ry. across C.N.R., at rail level, on Spruce Avenue, subject to and upon certain conditions. Pending installation of half-interlocking plant. City is authorized to operate cars over C.N.R. subject to condition that crossing be protected by watchmen to be appointed by C.N.R.; wages of watchmen to be borne and paid by city of Edmonton.

21939—May 29—Directing that C.N.R. widen loading platform at Vegreville, Alta., to 20 ft. within one month from date of this Order.

21940—May 28—Directing that C.N.R. construct and complete on or before July 1st, 1914, a one-pen stock yard and loading chute at Wiseton, Sask.

21941—May 29—Directing that C.N.R. file plan showing location of a fourth class station at village of Hughton, Sask., station to be erected and station agent appointed on or before July 15th, 1914.

21942—June 5—Authorizing Montreal and Southern Cos. Ry. to construct across parish line between parish of St. Paul de Abbotsford and parish of Granby, and public high-

ways known as Frith Road, between Lots 834 and 835, Cannan Road, between Lots [illegible] and [illegible], and Robinson Road, parish of Granby, Co. Shefford, Que.

2194[illegible]—June 5—Authorizing Essex Terminal Ry. Co. to open for traffic its railway from connection with C.P.R. to connection with M.C.RR. and Detroit Tunnel Company, town of Sandwich, Ont.

21944—June 5—Authorizing Lake Erie and Northern Ry. to construct reinforced retaining walls along Jubilee Terrace and Water St., city of Brantford, Ont., and span over its tracks for extension of Lorne Bridge.

21945—June 4—Granting leave to Okanagan Telephone Company to place its wires across Shuswap and Okanagan Ry. Co. at Okanagan St., city of Armstrong, and at Gore St., city of Vernon, B.C.

21946—June 2—Approving agreement, dated May 5th, 1914, entered into between Bell Telephone Co. and Bobcaygeon Rural Telephone Co., Limited.

21947—June 4—Extending collection and delivery limits of Dominion Express Co. in town of Banff, Alta.; and rescinding the Order No. 18740, dated February 20th, 1913.

21948—June 4—Authorizing G.T.P. Ry. to construct main line across Government Road, B.C., at mileages 241 and 245, Lots 2,400 and 7867, Yellowhead Pass West, Cariboo Dist, B.C.

21949—June 4—Approving temporary diversion C.P.R. Main Line at mileage 39.3, Sudbury Subdivision, Lake Superior Div., and construct at grade, for period of 5 months from date of this Order; temporary diversion across North Road, Parry Sound, to Byng Inlet.

21950—June 2—Authorizing C.P.R. to construct, by means of grade crossings, Weyburn-Stirling Branch Line across fifteen (15) highways, between mileages 253.35 and 277.78.

21951—June 5—Authorizing C.L.I. and W. Ry. (C.P.R.) to construct, at grade, in town of Bowmanville, two (2) tracks across Scugog St., to proposed freight yard in Subdivision, Lots 145, 178, 179, 184 and 185, Block 1, said town; all switching movements across Scugog St., on said spur, be flagged.

21952—June 5—Authorizing C.P.R. (1) to revise grade of main line, Thompson Subdivision, crossing Lorne St.; (2) construct, by bridge, additional track (double track) of main line across Lorne St., Kamloops, B.C.; (3) to make revision of location of portion from mileage 0.22 to 0.55.

21953—June 5—Approving and authorizing clearances at spur for Crown Feed and Produce Co., at Calgary, Alta., subject to Company undertaking to keep employees off tops and sides of cars when operated over said spur.

21954—June 5—Authorizing C.L.O. and W. Ry. (C.P.R.) to construct, by means of grade crossings, its business spur across C.N.O.R. main line and spur at mileage 1.05 and 0.55 of spur, subject to and upon certain conditions; and rescinding Order No. 21481, dated March 13th, 1914, and Order No. 21740, dated May 4th, 1914.

21955—June 5—Authorizing city of Hamilton, Ont., at own expense, to construct and maintain Burlington St., or Base Line, being original road allowance for road between Lot 7, B.F. Con. and Con. 1, Tp. Barton, Co. Wentworth, now city of Hamilton, across portion of road allowance claimed by Hamilton Radial Electric Ry., as forming part of right-of-way.

21956—May 22—Directing G.T.R. to construct spur into premises of Hepworth Silica Pressed Brick Co., Limited, Hepworth, Ont., subject to certain conditions.

21957—June 8—Authorizing G.T.P. Ry. to construct bridge across Phillips Creek, mileage 102.2 Prince Rupert East, B.C.

21958—June 8—Directing that joint rate on coke, in carloads of a minimum weight of 40,000 lbs. per car, from Consumers' Gas Co.'s siding on Esplanade, Toronto, to sidings of C.P.R. at North Toronto, be reduced from 95 cts. to 60 cts. per ton of 2,000 lbs., effective not later than June 22nd, 1914.

21959—June 9—Directing that C.P.R. construct, at expense of Damase Goyotte of Lemoyne, Que., farm crossing [illegible] east of west switch of passing siding, parish St. Athanase, Co. Iberville, Que.; work be completed within 30 days from date of this Order.

21960—June 9—Approving location G.T.P. Branch Lines Co. station at Avonhurst, Sask., Sec. 26-19-16, W. 2 M., Melville-Regina Branch.

21961—June 9—Authorizing G.T.P. Ry. to construct bridge across Ksi-Den Creek, mileage 147.3, Prince Rupert East, B.C.

21962—June 8—Authorizing G.T.P. Ry. to construct bridges across Fiddler Creek, mileage 127; Porcupine Creek, mileage 133.5; Lorne Creek, mileage 129; and Kitwanger Creek, mileage 152, Prince Rupert East, B.C.

21963—June 8—Extending, until November 4th, 1914, time within which G.T.R. complete spur into premises of Dominion Stove and Foundry Co., Limited, town of Penetanguishene, Ontario.

21964—June 8—Authorizing C.N.O.R. to construct spur to ballast pit across public road between Cons. 1 and 2, Tp. Pembroke, Co. Renfrew, Ontario, and operate same for 3 years.

21965—June 9—Approving location C.N.O.R. station at Ste. Dorothee (Isle Jesus), Co. Laval, Que., mileage 39, Hawkesbury East.

21966—June 6—Authorizing Edmonton, Dunvegan and B.C. Ry., to construct across thirteen highways in Province of Alberta.

21967—June 9—Relieving M.C.R.R., and Pere Marquette R.R. from erecting and maintaining fences on boundary line between respective rights of way on south side M.C.R.R. and north side of P.M.R.R.) at points west of St. Thomas, Ontario.

21968—June 9—Ordering the Dominion Express Co. to publish and file special tariff applicable to through shipments of milk or cream to Boston, Mass., establishing certain rates.

21969—June 11—Dismissing applications of Sheldons, Limited, Galt, Ont., and the Sirocco Co., of Windsor, Ont., for an Order reducing the carload rating of heating and ventilating apparatus in the Can. Freight Classification from 5th to 6th class.

21970—June 5—Authorizing the Lake Erie and Northern Ry. Co. to construct its railway across the highway between Cons. 8 and 9, Station 914-61.7, at mileage 37.36, Tp. of Townsend, by means of a subway.

21971—June 9—Authorizing the C.L.O. and W. Ry. to construct, maintain, and operate a business spur from a point on its main line in Trenton, Ont., at mileage 87.46 from Glen Tay, equal to mileage 0.00 of the proposed spur, to a point in Lot 1, on the northwest corner of Ontario and Dundas Sts., in said town, at mileage 0.00 and station 42-85.7 which is equal to Station 26-23.2 of the spur as originally located.

21972—June 8—Authorizing the C.P.R. to construct, maintain and operate branch line of railway, or spur, for the Canmore Coal Co., Canmore, Alta., from a point on existing spur in the S.E. ¼ of Sec. 29, Tp. 24, R. 10, west 4th Mer., on C.P.R. main line at Canmore, Alta.

21973—June 9—Approving revised location of a portion of the C.P.R. Co.'s Swift Current North Westerly Branch line from a point in Sec. 2, Tp. 23, Rge. 27, west 3rd Mer., at mileage 94.64, to a point in Sec. 3, Tp. 23, R. 27, W. 3 M., at mileage 97.29, and from a point in Sec. 3, Tp. 23, R. 29, w. 3rd Mer., at mileage 109.10, to a point in Sec. 17, Tp. 23, R. 29, W. 3 M., at mileage 111.95 of Swift Current North Westerly Branch Line.

21974—June 8—Further extending the time within which the C.P.R. complete the sidings for the Godson Contracting Co., Tp. Darlington, Co. Durham, Ont., until September [illegible]th, 1914.

21975—June 9—Ordering the C.P.R. to divert crossing into the highway of the public road just west of Armilla, Sask., about eight hundred ft. east therefrom.

21976—June 1[illegible]—Ordering the G.T.R. to switch cars, when desired by the municipality, to and from the track on the Esplanade owned by the town of Cobourg.

2197[illegible]—May [illegible]—Amending Order No. [illegible], October [illegible]th, 1913, by substituting the plan marked "A," dated November [illegible], 1913, for the plan dated July [illegible]th, 1913, approved under the said Order.

Volume 26. Toronto, June 25th, 1914

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

PROVENCHER BRIDGE, ST. BONIFACE, MAN.

GENERAL DESCRIPTION OF DOUBLE-LEAF BASCULE BRIDGE TO BE ERECTED OVER THE RED RIVER BETWEEN ST. BONIFACE AND WINNIPEG.

TENDERS have been called for the supply and erection of the superstructure for a bridge to cross the Red River between Provencher Avenue, St. Boniface, and Water Street, Winnipeg. The superstructure is to be a double-leaf, Strauss trunnion, bascule bridge, spanning a 105-foot channel on a 60° skew. The bascule span is to consist of two through girder-spans, the main trunnions of which are supported on two trunnion posts for each girder. The construction further includes two towers, in addition to reinforced concrete counter weights, supported from the tail ends of the girders and maintained in a horizontal position during the operation of the bridge by means of structural steel counter weight lengths.

The live load uplift is taken by supports in the front and by supports in the rear connected to the approach spans.

The machinery for the operation of the bridge embraces trains of gears operated by electric motors and actuating operating pinions, one for each girder, engaging segmental cast iron racks bolted to the tail ends of the girders. The motive power is to consist of 4 electric motors for general operation of the bridge and additional motor for the operation of the centre locks. They are to be series wound and of the enclosed railway type. Each motor is to be furnished with a brake held in the set position by a spring strong enough to overcome about 135 per cent. normal motor torque and to be released by enclosed solenoids and held automatically in release. The equipment is also provided with a hand-brake. The control of the leaf motors and of the centre lock motor will be quickly interlocked with each other in such a way that it will be impossible for the operators to start the leaf operating motors until the locks have actually been released; also in closing it will be impossible for the operator to close the locks until the bridge has been completely closed. This interlocking is accomplished, not by mechanically locking levers, but by preventing the operator to get current into his motors until the preceding motion has actually been performed. An automatic cut-off will throw the circuit-brakers out on the operating motor circuits and set their brakes when the bridge reaches nearly its open or its closed positions. The electrical equipment is so designed that each leaf can be operated from its adjacent operator's house. The centre lock mechanism is to be operated from one of these also.

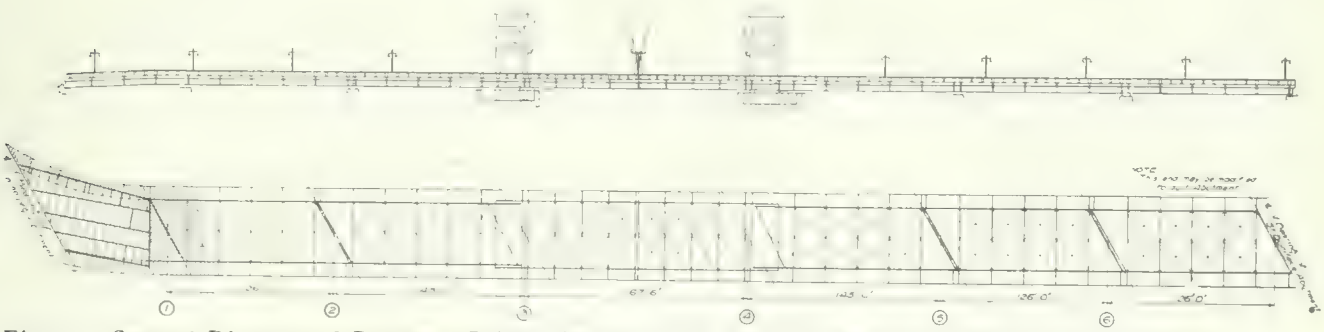

Fig. 1.—General Diagram of Proposed Bridge Over the Red River, Between Winnipeg and St. Boniface.

Reinforced concrete counter weights will be used, and, as stated, will be connected to the tail ends of the bascule girders. Each will be in the form of a monolithic concrete block, with recesses for additional material for adjustment, and will be supported on a structural steel frame. The concrete mix will be 1 of Portland cement: 8 of sand and crushed stone, and will weigh about 148 lbs. per cubic foot. Altogether there will be about 2,338 cu. yds. of concrete, including reinforcement in the counter weights.

The bridge floor will have a clear width of roadway of 44 ft. between the main girders. Two sidewalks, each 19 ft. in width, will be carried on steel brackets outside of the main girders. The bridge will be provided with two lines of car tracks, spaced 11 ft. 9 in. from centre to centre of the tracks, and it will provide head room to suit the trolley wires being placed 18 ft. from the top of the rails. The dead load will thus consist of the weight of the steel in the girders, floor system, hand-rails, laterals, etc., the weight of concrete in sidewalks and floor and the weight of pavement, rails, etc. The

...ain girders are proportioned to carry the following loads:—

Portion of span in ft.	Lbs. per cu. ft. in each car track.	Lbs. per sq. ft. of remaining floor, including walks.
100	1,800	100
110	1,740	98
120	1,680	96
130	1,620	94

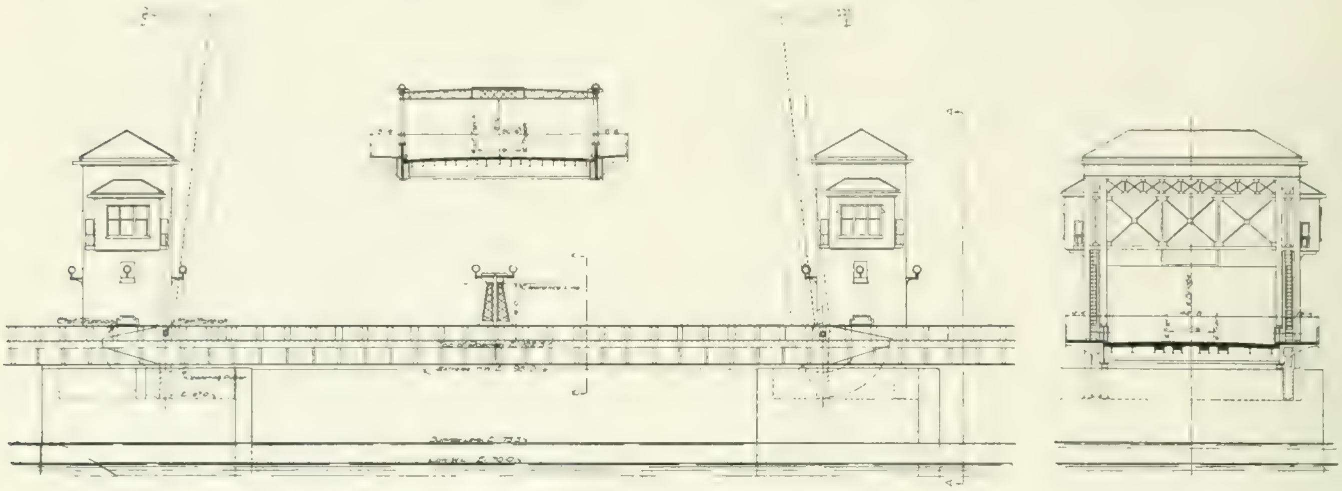

Fig. 2.—Elevation and Sections of the Bascule Section of the Provencher Bridge.

The floor beams are designed for a concentrated load of 30 tons on two axles, 14 ft. apart, for each car track, assumed to occupy the width of 11 ft. and 100 lbs. per sq. ft. remaining floor surface. Stringers are designed for a concentrated live load of 15 tons on two axles, 14 ft. centres and 16 tons, 10 ft. centres. A uniform load of 100 lbs. per sq. ft. is the basis of the sidewalk stringer and bracket design, while the floor slab on roadway is proportioned to support a concentrated load of 3 tons per foot in width of the slab.

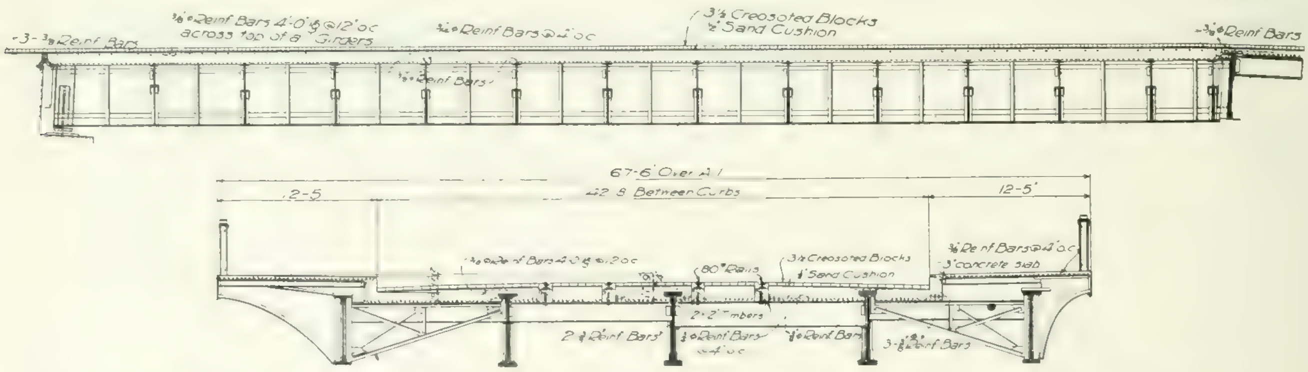

Fig. 3.—Longitudinal and Cross-sections of Span Between Abutment on the Winnipeg Side and Pier I.

Specifications consider the reinforced concrete floor and floor beams to have a sufficient bracing for wind load. A temperature variation of 150° F. is provided for, and the traction load is estimated at 20 per cent. of the greatest live load on any part of the structure. The impact load is taken as a percentage of the live load, equal to $\frac{10,000}{L + 150}$ where L is the length and feet of portion of span covered by the live load when the member considered receives its maximum stress.

The floor of the bridge will be of reinforced concrete, 6 in. in thickness, and supported on steel stringers, the reinforcement to consist of plain, round rods placed at right angles to the centre line of the bridge. The floor mix will be 1:2:4. The surface will be crowned 3 in. from sides to centre. The specifications call for a cement and sand cushion ½ in. thick with a 3½ in. creosoted wood block pavement or an alternative No. 1, sheet asphalt on the fixed spans, this to have a 2-in. surface on a 1½ in. binder.

It has recently been announced that alternative tenders will be considered on other designs for this bridge to comply with the specifications. If trusses are used in them instead of plate girders it is necessary, however, that they be not over 14 ft. in height.

The work is to be completed by Nov. 1st, 1915. The bridge itself is designed by the Strauss Bascule Bridge Co., of Chicago. Col. H. N. Ruttan is consulting engineer of the work. M. P. Blair, city engineer of St. Boniface, will supervise its erection.

SEVENTH CONGRESS OF THE INTERNATIONAL ASSOCIATION FOR TESTING MATERIALS.

The Seventh Congress of the International Association for Testing Materials will be held under the patronage of H.M. the Czar of Russia, in St. Petersburg, from August 12th to 17th, 1915. Four days will be devoted to the discussion of the most important problems on testing materials. After the Congress extensive excursions in the interior of Russia have been arranged.

The president of the Association is N. Belelubsky, St. Petersburg; vice-presidents, A. Martens, Berlin; A. Mesnager, Paris; G. C. Lloyd, London; R. W. Hunt, Chicago, and general secretary, E. Reitler, Vienna.

TYPES OF FLOORS FOR LIGHT HIGHWAY BRIDGES.

IN the latest annual report of the Illinois State Highway Commission the question of floors for steel highway bridges is reported upon. The suggestions given concerning them are given below:

The largest item of expense in connection with the upkeep of steel bridges not having concrete or other permanent floors, is that of floor maintenance. Until a few years ago, the floor almost universally specified for country highway bridges consisted of white or burr oak plank, from 2½ to 3 inches in thickness. When first-class material could be obtained at a cost of $25 per thousand feet board measure, such floors proved to be fairly economical if not subjected to heavy traffic. But now it is almost impossible to obtain at any price a good quality of white or burr oak bridge plank.

The lightest concrete floor that can be designed to carry modern traffic with safety weighs 40 pounds or more per square foot, and in order to protect such a floor from excessive wear and to distribute concentrated loads sufficiently so that they will not produce local failure, a wearing surface of gravel, macadam or brick weighing a minimum of 50 pounds per square foot is necessary.

Steel bridges carrying plank floors are rarely, if ever, designed to carry more than the dead weight of the bridge itself, which includes about 12 pounds per square foot for the floor, and a live load of 100 pounds per square foot, provided by law.

To place a concrete floor on a steel bridge, designed to carry a plank floor, would impose, therefore, an additional dead load on the structure amounting to the difference between 90 pounds per square foot, the weight of the concrete floor and wearing surface, and 12 pounds per square foot, the weight of a plank floor, or about 78 pounds per square foot.

The proposed floor must weigh but little more than the floor for which the structure was designed; it must not be unduly expensive, and it must be as durable as possible.

The material which best meets these requirements seems to be timber treated with creosote oil to prevent decay. All woods treated with creosote oil seem to resist decay equally well. Any wood may, therefore, be used which is susceptible to the creosote treatment and which will resist the wear coming upon it.

For existing wood floor steel bridges, located in or near cities, which carry a considerable amount of traffic, it is recommended that a creosote wood block pavement be laid on creosoted pine sub-plank. Such a floor weighs about 30 pounds per square foot. This is about 18 pounds per square foot in excess of the floor weight a majority of wood floor steel bridges are designed to carry. However, as this type of floor is very much smoother and stiffer than the ordinary plank floor, the reduction of vibration due to heavy moving loads is greatly decreased. This is a factor of safety which will balance somewhat the greater dead weight of the structure. However, a careful investigation of the strength of the bridge should be made before a floor of this character is laid.

At present prices for material this type of floor can be laid for about four times the cost of a 3-inch plank floor. If proper materials and workmanship are used, there is little question but that such a floor will last 12 years or more, possibly 25 or 30 years.

For existing bridges in good condition and of proper design, located on roads at some distance from a city, carrying a moderate amount of traffic, a floor consisting of 3-inch creosoted sub-plank on which is placed a wearing surface about three-quarters of an inch thick of fine gravel or stone chips flushed with heavy asphaltic filler will be found serviceable and economical. Such a floor, if properly constructed, will present a smooth, elastic surface which will reduce vibration. A floor of this character weighs but a few pounds per square foot more than a 3-inch oak plank floor and is far more durable. The wearing surface will probably require renewal at intervals of from 2 to 6 years, depending upon traffic conditions. As the wearing surface may readily be renewed by day labor, at a cost of about 50 cents per square yard, the item of maintenance is small compared with the cost of maintaining an untreated plank floor. There is no reason why a floor of this character should not last as long as a creosoted block floor, providing the sub-plank is kept protected from wear by a properly maintained wearing surface.

For existing country highway bridges, in good repair and of sufficient strength, where traffic is light and little wear comes upon the floor, creosoted oak plank with no special wearing surface can often be used. Red oak can be used to advantage for this purpose, as it is readily susceptible to treatment with creosote oil, wears less than a softer wood and will probably last as long, as far as decay is concerned, as any other creosoted timber.

In this connection it is worthy to note that the rate of wear on an ordinary plank floor greatly increases with the age of the plank, owing to the softening of the wood as decay advances. As the creosote treatment protects the plank from decay, a floor of this character will wear better than a floor of untreated material, as the wood remains hard and resistant until decay sets in.

In the light of the above discussion it is, therefore, well to hold in mind the following points:

1. Old steel bridges are rarely, if ever, strong enough to carry with safety a concrete floor.

2. For existing steel bridges in good condition and of satisfactory design, located in cities or elsewhere where traffic is heavy and ordinary plank floors rapidly wear out, it will be found economical to refloor with creosoted sub-plank and creosoted blocks.

3. For existing steel bridges in good repair and of satisfactory design, carrying moderate traffic, but yet where wear is of considerable importance, it will be found economical to use creosoted plank with a bituminous wearing surface.

4. For existing steel bridges in locations where an ordinary plank floor rots rather than wears out, a creosoted plank floor with no special wearing surface will be found economical.

If a proper selection of floor is made, and the material used is subjected to rigid specifications and inspection, this floor should in most cases outlast the steel bridge on which it is placed.

A proposal is on foot to build a bridge across the harbor of North Sydney, Australia, in conjunction with a new underground railway system. This bridge will be the third largest in the world as regards length of span, and the first as regards headway for shipping. The specification provides that it shall consist of nickel-steel cantilevers supporting centre girders, also of nickel steel. The shore arms of the cantilevers will be some 500 ft. long, and the cantilever arms 520 ft. long, the length of the centre girder being 560 ft. The approaches to the bridge will consist of steel arch spans of the three-hinged spandrel braced type.

THE METHODS AND WORK OF THE EMSCHER-GENOSSENSCHAFT.

By Prof. P. Gillespie, C.E., University of Toronto.

THE Emscher River is a tributary of the Rhine, the confluence being 12 miles below Essen, famous as the headquarters of the Krupp steel industries. The stream has an average discharge at its mouth of 300 cubic feet per second, a volume equivalent to one-seventh of that of the Canadian Trent at low water. It drains an area of 300 square miles which supports a population upwards of 2,000,000 people; so that the number of persons to the square mile is over 6,600. If the entire population of Canada were placed on the province of Prince Edward Island, the congestion would be less than half that obtaining in the Emscher valley. Predominatingly industrial is the district owing to the prevalence of coal deposits and mines and the stimulus which these give to the manufacture of iron, steel and steel products. The larger centres are Oberhausen, Essen, Gelsenkirchen, Bochum, Recklinghausen and Dortmund. The seriousness and complexity of the problems involved in the satisfactory drainage of such a district will readily be appreciated, but here, as elsewhere, the situation seems to have developed both the men and the method.

In 1906 an act of parliament passed by the Prussian government created the so-called Emschergenossenschaft or Emscher Federation and conferred upon it wide powers and much authority. On this board are represented the government, the municipalities, the mines, the industries and the farmers. Its work comprises the regulation of the Emscher River and its tributaries and the design and construction of bridges, sewers and sewage disposal works. It has authority to levy rates for these undertakings and to that end, to make assessments in which the responsibility for nuisance and the benefit to be derived from its amelioration are the determining factors in the award. Dr. Karl Imhoff is the chief engineer of the sewage division of the federation's work, and it was under his direction that the work of perfecting that type of clarification tank which bears his name and which has come to be regarded as the feature of the Emscher method of sewage treatment, was carried out. The Emscher Federation is a splendid example of effective organization and efficient management and is successfully executing a work which could not have been carried out by independent effort except at enormous waste of energy and money. It has expert service to apply to the solution of each individual problem; it eliminates the too-often costly experimenting of the novice; it secures economy; avoids unnecessary duplication, and is a happy compromise between public and private control. So pronounced are its advantages that one often wonders whether some of its methods and organization could not with great advantage be copied in this country. If our Provincial government with much acceptance can supply our municipalities with electrical energy, why can it not at least design our sewage disposal works? The latter undoubtedly touch the well-being of the community in at least as vital a way as the former.

The Emscher River is not generally a source of public water supply. In consequence the necessity for carrying the purification of sewage to the limit of excellence there, does not exist. In all cases, except in the upper reaches of the valley, the sedimentation of the sewage in Imhoff tanks combined with the subsequent treatment of the sludge constitutes practically the whole process. This makes for economy and simplicity of method and represents the general practice of the Board.

The first of the large Emscher plants was constructed at Recklinghausen in 1907. The Emscher year-book for the fiscal year ending March 31, 1913, states that at the time of its publication there were 19 separate plants within the jurisdiction of the Emschergenossenschaft comprising 123 Emscher tanks and serving in the aggregate 870,000 people. During the year then closing four urban communities, aggregating in population 210,000, had been supplied with clarification plants. This involved the construction of 34 Imhoff tanks exclusive of the doubling of the capacity of the old plant at Essen-Nordwest, also completed during the year. Mr. Leslie Frank, now with the Baltimore Sewerage Commission, who spent last year as a member of Dr. Imhoff's staff in Essen, states that in the German Empire there are probably 100 plants using the system. It has thus been tried out for seven years on a scale of great magnitude in Germany and so successful has it proved that a federation similar in its organization to the Emschergenossenschaft has recently been formed for the watershed of the Rhur, adjacent to the Emscher valley. This stream is another tributary of the Rhine with a flow ten times that of the Emscher and a drainage area six times as large. Of this, Dr. Imhoff is the chief engineer. Construction was begun there a year ago.

A visit to the works under Dr. Imhoff's care confirms all that has been said from time to time regarding the results which are attained there. The Imhoff tank is primarily a device for the inoffensive treatment of sludge and it is to that device that the visitor's attention is naturally directed. An attendant opens one of the sludge valves allowing the liquid sludge to escape. In color it is always black. Although its water content is less than that of fresh sludge by 20%, it is more mobile than the latter and flows freely. Its odor is that of hot asphalt or scorched rubber. So distinctive is this, that by the smell, properly rotted sludge may be readily identified. The smell of sour milk so characteristic of insufficiently decomposed sludge is here entirely absent. Especially noticeable is the rapidity with which the sludge separates from its water. This is one of the most important, and from the engineer's standpoint, one of the most fortunate of its characteristics. On the sludge-drying bed the sludge floats to the top and the water sinks to the bottom and drains away through the sand or cinder layers below. It is interesting to observe that while the sludge-drying area is in Germany ⅓ sq. ft. per inhabitant, in Birmingham it is 2 sq. ft.

The visitor's attention is attracted to the active and constant ebullition taking place in the gas vents to the digestion chambers. The liquor there is inky black and the escape of gas is most vigorous though not offensive to the sense of smell. It is commonly stated that this gas is roughly ¾ methane and ¼ carbonic acid gas, but the writer has not seen any analyses that could be considered the results of precise work, though doubtless such are available. Over one of the rectangular vents at the plant at Essen-Nord, a metallic hood terminating in a gas-pipe has been erected. The escaping gas, if ignited, will burn continuously. This plant, by the way, is the largest controlled by the Emscher Board, serving as it does a population approximately three-eighths that of Toronto. The sewage is a mixture of domestic and industrial since the Krupp steel works and other large industries are located there. There are eighteen Emscher tanks in all, twelve of the longitudinal flow and six of the radial

flow type. There is no offensive odor. In the immediate neighborhood are the plant of the Rhenish Westphalian Electrical Company and the dwellings of the workmen. Some of our municipal authorities will be interested in the fact that the per capita charges for interest, sinking fund, administration and maintenance are less than five cents per annum.

Some doubts have been expressed as to the likelihood of Emscher tanks working efficiently in this latitude because of the much lower temperature. These misgivings, in the view of the writer, are without much foundation. In the first place, let it be remembered, the temperature of sewage does not fluctuate markedly in response to temperature changes in the atmosphere. The reason for this is obvious, particularly where the community is sewered on the separate system. The sewers are buried in earth whose temperature is nearly constant. Furthermore, the opportunities for fluctuation of temperature in the decomposing chamber of an Emscher tank are very much less than in an ordinary sedimentation or septic tank. The decaying process in the former takes place under 25 feet of nearly stagnant water and into this digestion chamber almost no fresh sewage is permitted to enter. It is interesting to observe, moreover, that there is less than 5 deg. F. difference between the mean annual temperatures of Toronto and Essen, Germany. In the second place, it must not be forgotten that the activity of sludge decomposition depends upon many influences other than temperature, as the experiments of Guth and Spillner in 1911 have shown. In this series, observations were made on the manner in which decay of organic substances takes place in sewage tanks of various types. At thirteen different stations, all of them within a triangle determined by Hamburg, Essen and Leipzig, and representing every possible kind of sewage, parallel tests were made. The average temperatures over a period of eight weeks are reported as varying from 48 deg. F. in the sewage disposal plant at Harzburg, to 71 deg. F. in the Emscher tank in the sewage disposal plant in Essen-Nordwest. On the whole, the most complete digestion took place at a station in Hamburg, where the temperature was about 60 deg. F. Of the 13 tank temperatures, four were higher than this one. In the third place, observation shows that at the plants of two adjacent communities sewage temperatures at the same time may sometimes differ very much more than the fluctuations of either between summer and winter seasons. To minimize this latter variation in this country, it will often be advisable to provide covers.

That the dried sludge has some manurial value is evidenced by the fact that farmers are willing to take it at a small price for use on the land. At Recklinghausen it brings 12 cents per cart load; at Erfurt (not in the Emscher district) it sells at 7½ cents per cubic yard. On the sludge dumps about the Emscher plants, it is a common sight to see luxuriant vegetation. In contrast with this is the appearance of the dried sludge banks at Birmingham which support not a single blade of grass. The presence of copper and other metallic salts in considerable quantities in the sewage of the latter place is thought by some to be the explanation.

It is significant that the supposed failures of the Imhoff system are not in the Emscher valley. Indeed, some of the alleged failures elsewhere investigated by the writer, were found to be working excellently. The skilled supervision received from the operating staff of the Emschergenossenschaft assists materially in bringing to a satisfactory working state the plants under its control. Probably the lack of it elsewhere explains why satisfactory working conditions are so long deferred in a few other plants. The writer found one Imhoff tank installation in central Germany which produced a good inoffensive sludge for the first time three years after being put into operation. Needless to say, the plant was not under the supervision, directly or indirectly, of the staff of the Emschergenossenschaft.

Of the Imhoff tank, several modifications and adaptations have come into being. One of these is exploited by the holders of the Kremer patents, the Sewage Purification Company of Berlin, who have adapted their fat-arresting device to the double-story tank of the Imhoff type and who claim to have installed over 50 large purification plants for towns, communities and institutions. Another is the Städtereinigung und Ingenieurbau A. G., of Wiesbaden and Berlin, selling under the cryptographic commercial designation of "Stiag." A somewhat similar state of affairs exists on this side of the water.

In the United States some 25 cities, towns and institutions have constructed Imhoff tanks. Rochester, N.Y., one of the latest, is planning for 20 tanks to serve a population of 400,000. In Canada, a few have been or are being built. In England, outside of Dr. Travis' hydrolytic tanks at Norwich, Hampton and Luton, not one known to the writer has been or is being constructed. Dr. Fowler, of Manchester, and Mr. J. D. Watson, of Birmingham, have constructed experimental tanks of the Emscher type at the sewage disposal works of those cities. With typical conservatism, the Britisher prefers to wait until he is absolutely sure of his ground.

The writer regards the Imhoff tank as representing the most significant advance made in the art of sewage purification during the past ten years. This not because of small initial cost or ease of construction, neither of which it probably possesses, nor because in the general case it constitutes a method of sewage treatment complete in itself, for it does not, except in special cases like the Emscher valley, but because it affords an undoubted solution to that most troublesome phase of sewage treatment—the disposal of sewage. To anyone who has encountered the penetrating stench emanating from putrefying sewage as it exists at many plants, the extra cost will be justified. Moreover, the favorable representations made by visitors to the German plants regarding this odor question have not, in the opinion of the writer, been exaggerated.

What the future has for the art of sewage treatment it is impossible to say, but since, at the hands of specially trained investigators in Europe and America, the problem is receiving much attention, it cannot be believed that a finality has been reached. But even if no improvement upon existing processes were to be realized, the methods of to-day are producing results which, in the main, are satisfactory, and which are available to all our cities and towns at moderate cost.

A feature of the prospectus just issued by the Lucky Strike Oil and Gas Company, Limited, of Calgary, Alta., is the fact that the company proposes drilling for oil and petroleum gas at or near Aldersyde, close to a well that is now producing petroleum gas at a depth of only 280 feet. The company will drill a number of wells until a flow of 4,000,000 feet of gas is obtained. Bessemer condensers will be installed for the purpose of extracting the gasoline, and at the low estimate of 25 cents per gallon, it is anticipated that the revenue of the company from this source alone will amount to $1,000 daily.

CRITICAL LOADS FOR IDEAL LONG COLUMNS.*

By Arthur Morley.

(Concluded from last week.)

EXAMPLE IV.:—

As a nearer approximation to a practical shape, take a column of uniform type of section, but the linear cross-sectional dimensions varying uniformly from the fixed to the free end at which they are half those at the fixed end—e.g., a conical pillar—

$$I = I_1 \frac{(l + x)^4}{16\, l^4} \qquad . \quad . \quad . \quad (31)$$

Assuming the curve (2) the successive approximations to P are $\frac{E\, I_1}{l^2}$ multiplied by $3/2$, $15/14$, $147/142$, etc., or 1.5, 1.071, 1.035, etc., respectively.

If we assume as a starting point

$$y = y_0 \qquad . \quad . \quad . \quad (32)$$

which, as a second approximation, yields the curve taken under the action of the couple $(P\, y_0)$ at the free end of the corresponding cantilever—viz.—

$$y = y_0 \left(\frac{l^2}{2(l + x)^2} + \frac{x}{2\, l} - 1\right) \qquad . \quad (33)$$

the successive approximations for P are $\frac{E\, I_1}{l^2}$ multiplied by ¾, 30/31, 31/32, etc., or 0.75, 0.96774, 0.96875, etc. The limit is evidently approached very quickly, and it may be taken as very near to $0.97 \frac{E\, I_1}{l^2}$. In any case it has been reduced to the range between 1.035 and 0.97 times $\frac{E\, I_1}{l^2}$.

Economy of Material.—If A_1 is the cross-sectional area at the fixed end, the volume of the column in Example IV. is $\frac{7}{8} \times \frac{1}{3} A_1 \times 2\, l = \frac{7}{12} . A_1\, l$. A column of uniform cross-section and the same volume has a moment of inertia of cross-section equal to $\left(\frac{7}{12}\right)^2 \times I$, and its critical load is $\frac{\pi^2}{4\, l^2} . E \times \left(\frac{7}{12}\right)^2 I_1 = 0.84 \frac{E\, I_1}{l^2}$, or some 13 per cent. less than that of the tapered column. On the other hand, considering the more tapered column of Example III., its volume is ½ $A_1\, l$. A uniform column of equal volume would have a critical load of $\frac{\pi^2}{4\, l^2} E \times \frac{1}{4} I_1 = 0.616 \frac{E\, I_1}{l^2}$, or nearly 2½ times that of the tapered column (which is $\frac{1}{4} \frac{E\, I_1}{l^2}$).

Curve Approximations. The statement has been made that the exact shape of the curve is not important. But it has been shown in the foregoing that while the difference in end-loaded cantilever and column curves is not so great in columns of constant moment of inertia as to give a bad approximation, the case may be very different

Fig. 2.

with tapering columns. It may be worth stating the point from simple principles as follows:—

1. It is clear from the bending moment diagrams, say, A1 B and A C B, Fig. 2, which for equal values of y_0 must have equal moments about O, that the curvature will be greater for the column than for the cantilever, for the bending moments are increased in greater proportion where their values are smaller—i.e., towards the free end.

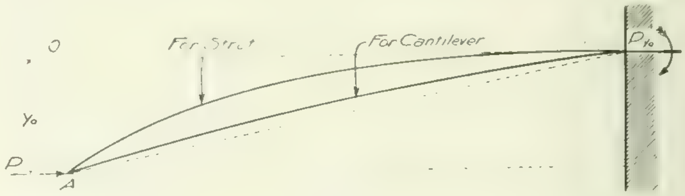

Fig. 3.

2. This is particularly the case with tapering columns, for here I decreases:—

$$\left(\frac{d^2 y}{d\, x^2} = \frac{M}{E\, I}\right).$$

3. For the displacement method—

$$y_0 = \int_0^l \frac{M\, x}{E\, I} d\, x = \frac{P}{E} \int_0^l \frac{(y_0 - y)\, x}{I} d\, x,$$

or

$$P = E\, y_0 \div \int_0^l \frac{(y_0 - y)\, x}{I} d\, x.$$

For any curve flatter than the true one

$$\int_0^l \frac{(y_0 - y)\, x}{I} d\, x$$

is underestimated, and therefore P is overestimated.

4. By the method by energy, for a curve flatter than the true one (see Fig. 3), the strain energy is underestimated, but the axial component of the movement of P is underestimated in a greater proportion; hence, from the equation P = (strain energy) ÷ (axial movement of P), P is overestimated.

Note on the Initial Choice of a Curve.—By choosing a straight line or the second approximation to which it leads—viz., the curve of an end loaded cantilever—a curve flatter than the true curve is ensured and the true critical load is approached from above. By starting from a constant deflection or the curve of a cantilever acted on by a couple at its free end to which it leads, a curve of exaggerated curvature is secured and the true critical load is approached from below. If the limit is approached

*Reproduced from April 24th issue of Engineering (London).

slowly, the use of both alternatives, when possible, may be recommended.

An alternative method of obtaining a starting point corresponding to the second approximation is to assume that the curve is of the form

$$y = y_0 \left(A + B\frac{x}{l} + C\frac{x^2}{l^2} + D\frac{x^3}{l^3}\right) \quad . \qquad (34)$$

the number of constants being equal to the number of known conditions and powers of x higher than the third vanishing when $\frac{d^4 y}{d x^4} = 0$ for all values of x. If the coefficients A, B, C, etc., are made to comply with as many of the known end conditions as possible, the resulting approximations for the curve and for the critical load will be closer than those from a curve complying with fewer of these conditions.

Thus, in Example I., for $x = 0$, $y = y_0$; therefore $A = 1$. Also $\frac{d^2 y}{d x^2} = 0$; hence $C = 0$. And for $x = l$, $y = 0$, and $\frac{d y}{d x} = 0$; hence $B = -3/2$, $D = 1/2$, from which (34) reduces to equation (7). The resulting coefficient for P—viz., 2.5—is nearer the true value, although not safer, than if we neglect the condition $\frac{d^2 y}{d x^2} = 0$, which from the general form

$$y = y_0 \left(A + B\frac{x}{l} + C\frac{x^2}{l^2}\right) \quad . \qquad (35)$$

yields the form (17) and a coefficient 2.4. Similarly, in Example III., in which $\frac{d^2 y}{d x^2}$ is not necessarily zero, the form (2), which corresponds to $A = 1$, $B = -1$, $C = 0$ in (35) gives coefficients 1, ½, 2/5, 5/14, etc., while the nearer form $A = 1$, $B = -3/2$, $C = ½$, resulting from the three conditions $y = y_0$ for $x = 0$ and $\frac{d y}{d x} = 0 = y$ for $x = l$ gives the nearer coefficients 2/3, 6/13, 26/67, 134/381, which, however, approach the same limit, but in a manner somewhat less simple to compute arithmetically.

The United States Bureau of Mines has undertaken to construct, in co-operation with the mining industry and the manufacturers of mining machinery, a mine beneath the floor of the Palace of Mines and Metallurgy at the Panama-Pacific Exposition. The financial and operative success of the mine is assured through exhibits whereby typical metal and coal mining operations will be reproduced by full size working places in which mining machinery will be installed and operated. The walls of the mine will be covered with either ore or coal typical of the mine illustrated.

The American Society of Engineers, Architects and Constructors was incorporated in New Jersey in May last, in the interests of civil engineering, architecture, engineering and building construction, and the arts allied thereto. Its board of trustees consists of Messrs. J. W. Howard, C.E., O. R. Parry, J. A. Yates, C.E., C. F. Dingman, W. P. Comstock, A.B., J. R. Draney and T. H. Boorman, C.E. At the election of officers Major S. S. Hatfield, C.E., became president and Mr. T. H. Boorman, C.E., secretary. We note among the associates of the society the names of Messrs. E. Belanger, C.E., Montreal, and D. D. Barry, Government engineer, Ottawa.

MOTOR BUS TRAFFIC—ITS DEVELOPMENT AND CHARACTERISTICS.

At the recent National Conference on City Planning, held in Toronto, Mr. John A. McCollum, assistant engineer, Board of Estimate and Apportionment, New York City, read a paper on the use of the motor bus by municipalities, and outlined many important points in connection with it in the solution of transportation problems. The following is, in part, Mr. McCollum's paper:—

The date of the first appearance of the horse-drawn omnibus in London is not definitely known, but it is certain that corporations owning and operating such vehicles were in existence as early as 1855, and during the year 1862 more than 42,000,000 passengers were carried by the 600 vehicles of one company alone. The maximum number of horse-drawn vehicles was reached in 1901. In this year 3,736 were licensed. Subsequent to that time the number gradually decreased until a few months ago, when the last horse-drawn omnibus was removed from the streets of London.

The new era began in 1901, when 10 motor buses were licensed by the police. No large increase in numbers took place, however, until 1905, when 241 vehicles were licensed. From that time down to the present, the numbers increased by leaps and bounds. There are at present in London more than 3,000 motor-driven buses, which have entirely supplanted the horse-drawn vehicles. These have a seating capacity of 34 passengers each; operate on regular schedules; move with an average speed somewhat in excess of the surface railway cars, and carry with regularity and dispatch, at a rate of fare exceeding by only 20 per cent. that of the street railways, an aggregate of 676,000,000 passengers per annum, a total greater than the number of cash fares and transfers collected on all the street surface railways of the Boroughs of Manhattan and the Bronx in the city of New York. This seems miraculous when we consider the short period within which motor-driven vehicles have been developed and adapted to this severe use.

The operating efficiency of the motor bus in London may be well illustrated by the fact that during seven continuous months of the year 1913 about 2,200 motor buses ran an average of 117 miles each per day, or an aggregate of 55,000,000 bus miles, with a loss of schedule mileage equal to only 0.12 of one per cent. of the total. This probably exceeds the efficiency of many street railway systems. In Paris there are more than 1,000 vehicles of a type unlike those in London, operating under different conditions, but performing nevertheless an efficient passenger service. New motor bus routes are being established daily in European cities.

There are two characteristics of the motor bus which distinguish it from every other public transportation facility. The first is flexibility; that is, flexibility of vehicle movement and flexibility of route. Because of this feature the vehicle responds quickly to operating requirements and to traffic conditions; e.g., passengers may enter or leave buses at the side of the roadway without risk or danger of crossing dense vehicular traffic; delays to other motor cars do not result from breakdown either of a motor bus or any other vehicle, and daily or less frequent changes of route may be made to comply with traffic conditions. All of these are advantages not to be found in any car confined to rails.

The second distinguishing characteristic is its independence of extraneous equipment, such as expensive and delicate power generating and distributing systems or

expensive track equipment. The railway investment must, in a large measure, increase in the same ratio as the length of the track, while the motor bus investment grows only in proportion to the number of vehicles employed or, what is the same thing, in proportion to the daily vehicle mileage.

The importance of this feature is shown by the comparison of the capitalization of the street railways in the Boroughs of Manhattan and the Bronx and the municipally owned and operated surface railways in London with the largest omnibus undertaking in that city. The number of passengers carried in the year 1912 by the London railway was about the same as the number carried by its omnibus system. In Manhattan and the Bronx the total number of passengers paying cash fares and presenting transfers exceeded by about 20 per cent. the number carried by the London omnibus system. The aggregate lengths of route operated were about 148 miles by London railways, about 230 miles by Manhattan and the Bronx railways and more than 300 miles by the London motor buses. Yet at the close of 1912 the London railway investment, less the accumulated sinking funds, was $53,000,000; the Manhattan and the Bronx railways' capital was $190,000,000, with an appraised property. value of $166,000,000; while the amount of capital employed by the omnibus company, as evidenced by its outstanding securities, was only $15,500,000, including an increase during the year of $5,000,000 for the purpose of supplying funds for additional facilities, the benefit of which will accrue in subsequent years.

Thus we find that the London railway investment is about 3½ times that of the omnibus. The capitalization of the street railways in Manhattan and the Bronx is more than 12 times and their appraised value is almost 9 times as great as the capital used for London omnibuses. Five per cent. profit upon the capital of the railways of Manhattan and the Bronx would equal more than 13c. for each car mile operated. The following general comparisons may be made between the operating expense of the largest existing motor bus undertakings and that of the street railways:

In London, where the operation is skillfully managed, where the pavements are kept in excellent repair and where the improvement in the type and construction of vehicle has been most rapid, we find that the bare operating cost is relatively low. It is less than 15 cents per bus mile and probably does not exceed by more than 10 to 15% the cost per car mile of the municipally owned surface railways. The excess cost is, however, more than offset by the lower interest charges on motor bus operation, and the total cost per bus mile probably is less than the cost per car mile. The relative seating capacity of vehicles used in this comparison is 34 for the motor bus and 78 for the surface car. This ratio of seating capacity brings the total cost per motor bus seat mile greater than that of the car seat mile. In Paris, where a much heavier vehicle of about the same capacity is operated on pavements less smooth, the cost per mile is considerably greater than in London.

Many conditions abroad bearing on the cost of operation differ from those in America; e.g., the comparatively low cost of labor in England, particularly, mechanical labor, of which so much is required in motor omnibus operations.

The depreciation of the motor bus is much more rapid than that of the street railway car and other railway equipment and requires provision for replacement funds at a greater rate. The total amount of depreciation may not exceed that of the railway, although the rate is higher, because the value to which the rate is applied is much less. In London the life of motor bus equipment is estimated to be from five to six years, and in New York depreciation funds are provided sufficient to replace the vehicles after three years' use. Probably the average life of motor buses constructed abroad when efficiently maintained is much longer than five years, but the mechanical improvement in type and construction has been thus far so rapid that the vehicles become obsolete before they are worn out.

Street pavement is to the motor bus what the steel railway track is to the railway car, but unlike the railway track it is provided at public expense. Its preservation, therefore, is one of the problems which will confront the authorities if large numbers of heavy motor buses are to be operated, particularly in suburban districts, where the pavements are usually less permanent than in city streets with dense vehicular traffic.

The capacity—hence to some degree the weight—of the motor bus is an extremely important consideration from the standpoint of economy, for the cost of operation per vehicle does not increase at the same rate as the number of persons which it may carry. Therefore, where the volume of traffic is sufficient, a larger vehicle is more desirable. Speed and rapid acceleration up to certain limits are also essential for passenger service. In consequence, reduction of weight per unit capacity or other improvements in design must be depended upon to keep down road repair cost rather than reduction of speed in motor bus operation.

Motor buses operated in London, Paris and New York vary in weight from 219 pounds to 365 pounds for each passenger which the vehicle is capable of carrying. The lightest vehicle is used in London and weighs about 3¾ tons unloaded. This is the maximum weight permitted by the police for a public service vehicle. It is possible to obtain American-made single-deck buses, 24-passenger seating capacity, that probably do not exceed in weight the maximum per passenger capacity authorized in London. Whether those vehicles will prove successful in the severe trials of motor bus work is yet to be proven.

There is a great need for a careful research into the whole problem of mechanical traction on roads, particularly the effect of vehicle weight and speed upon the cost of road maintenance. If it is shown that the motor bus is particularly destructive to roads, the operators should pay something toward road maintenance.

BREAKWATER CONSTRUCTION AT VICTORIA.

In connection with the construction of a breakwater in the outer harbor at Victoria, B.C., a 7,000-ton floating dry dock, owned by the Seattle Construction and Dry Dock Co. and leased to Grant, Smith & Co., will be used. Upon it concrete piers will be built, the dry dock being allowed to sink as the construction of the piers progresses. When they have been completed, they will be held in suspension by cranes while the dry dock is being removed, after which they will be properly seated in position.

There are in all 54 of these caissons to be built in connection with the contract, two of them being constructed at a time upon the dry dock. Each will have a weight of approximately 3,500 tons.

The water level is regulated by means of water-tight compartments in the bottom and sides of the dry dock.

The Dominion Government will shortly spend $200,000 in establishing an astronomical observatory near Victoria. This station will be equipped with a 72-in. reflecting telescope, said to be the largest of its kind in existence.

POINTS IN ROAD DESIGN.

At the First Canadian and International Good Roads Congress, held in Montreal in May last (see *The Canadian Engineer*, May 28, 1914), the subject of road design was dealt with by Mr. Robt. A. Meeker, State Highway Engineer for New Jersey. Mr. Meeker touched upon the essential factors: width, alignment, grade and drainage, in the following way:

Width.—The first point to be considered in designing a road is its width. It may be generally stated as axiomatic that the width of roads should be in multiples of eight, this being the width that should be allowed for each vehicle using the road. A road 8 ft. wide might more properly be termed a lane leading to one building or a small group. The next in importance should be 16 ft. in width, in order that two vehicles might have sufficient width in which to pass. The third width, or 24 ft., would permit of two vehicles passing while the third was standing along the side of the road—or two loads of hay or other bulky material to pass. The fourth width, or 32 ft., permits two vehicles to stand along the sides and leaves sufficient space for two other vehicles, moving in opposite directions, to pass each other in safety. These widths refer to the traveled carriageway alone, no allowance whatever being made for the accommodation of pedestrians, nor for any drainage structures.

In order to obtain a roadway of sufficient width to accommodate travel passing in both directions, 24 ft. may well be taken as the minimum allowable, and if there is the prospect of an increase of traffic in the near future, a proper addition to the width of the surface, necessary for the accommodation of the traffic, should be provided for in the original design. It is almost impossible to properly grade and drain a road of less than 24 ft., and the wider the roadway the more easily it is drained, and also maintained, due to the fact that the traffic is distributed over a greater area, and that the surface is more freely exposed to the drying action of the wind and sun, thereby preventing the formation of mud and ruts.

Alignment.—The second problem is that of the location of the line. On a new road this is determined by certain well-defined principles. First, the beginning and ending points should be connected by the most direct line; second, the grades should be kept as low as possible; third, for economy's sake, the line should be so located as to reduce the amount of grading to the minimum, likewise the number and size of the bridges.

The factors governing the departure from a straight line are many. In crossing a ridge we seek the lowest point in the summit, in order to avoid expensive cutting or the alternative of steep grades; in following a valley we keep well up on the hillside, to avoid bridging ravines and small water courses; if we encounter a swamp or pond we can frequently, by swinging the line, save the expense of a heavy fill; a stream may be avoided by diverting the line, thus saving the cost of bridges.

On an old road another set of problems has to be solved; these are chiefly those of expediency. Though a straight line between the termini may not only be the best but also the cheapest, the claims of intermediate communities may be so strong that the line must be diverted from its best course to satisfy the wants of the communities to be served. But through it all, in spite of all of these warring factors, the engineer must never lose sight of the straight level line between two points as his ideal. By keeping this constantly before his mind's eye the results that may be achieved will often surprise even the author.

Grade.—The grade, or the angle which the axis of the road makes with a horizontal line, is the most important economic feature in road design, for upon it depends the amount of material a horse can draw over the road. The results of experiments made both in England and France prove that a horse can haul twice as heavy a load up a 2 per cent. grade as he can up a 6 per cent. grade. That being so, the value of a road for heavy traffic, having a maximum grade of 6 per cent., is only one-half of that having a maximum of 2 per-cent. This fact is often lost sight of in designing new grades, the object of many road officials being to build as many miles of road as possible for a given amount of money, the first cost, and not the ultimate value of the road to the community, being the basis upon which the improvement is made. This cutting down of hills and the filling of valleys or reduction of gradients is no new idea, for Isaiah wrote, over 2,000 years ago, his idea of a perfect highway as follows: "Every valley shall be exalted and every mountain and hill shall be made low; and the crooked shall be made straight, and the rough places plain."

Drainage.—Having laid out your road as straight as possible, and having reduced your grades as much as your funds will permit, the next important problem is is that of drainage. This is of two kinds—surface and subsurface. Surface drainage is both transverse and longitudinal. Every road must be so planned that the water which falls upon its surface will not remain upon or along it. The first object is attained by giving the road a proper crown or cross-section, so that the water may be conveyed quickly to the gutters on the sides. This crown should have the form of the arc of a circle, drawn through three points—the centre of the road and the gutter on either side. The elevation of these points should be in the following ratio: For earth roads a fall of 1 in. per foot from the centre to the gutters; for waterbound macadam, ¾ in. per foot, and for bituminous concrete ½ in. per foot. This form of cross-section permits of the fullest use of the road, and at the same time conveys the water to the gutters without washing the sides or shoulders of the road. The longitudinal surface drainage is taken care of by the gutters, which must be carefully trimmed to conform to the grade of road, all holes being carefully filled and all humps cut off. In fact, the gutters must be as carefully graded as the centre of the road. Proper inlets to bridges crossing the road should always be constructed if the bridge is as wide as the carriageway. In some soils these precautions are not sufficient, and we are then compelled to lay underdrains. These should be placed about 3 ft. inside of the gutter line, for two reasons: First, to intercept the subsurface water before it reaches the middle of the road, and second, to prevent erosion in case the gutters are gullied. The object of underdrains is to cut off the subsurface water before it can get beneath the traveled road; therefore their place is on one or both sides of the paved way.

The second-hand railway equipment business of Jas. T. Gardner, deceased, Chicago, will continue under the name of Jas. T. Gardner, Inc., with the following officers:—M. Gardner, pres.; R. H. Gardner, vice-pres.; A. V. Talbot, sec.; and A. M. Talbot, treas.

Victoria, B.C., has commenced work on the excavation of the ten-mile trench in which the steel pressure pipe for the Sooke Lake waterworks system will be laid from Humpback Reservoir to the city. This work will be rushed ahead in order that no delay may be encountered when the Burrard Engineering Company of Vancouver, to which has been let the contract for the fabrication and laying of the pipe, starts delivering the pipe lengths.

THE FIRST RAILROAD IN AMERICA.

THE pressing need for additional and enlarged transportation facilities to meet the growing demand occasioned by the phenomenal growth of business in all of its departments and branches, presents itself as an issue and problem of far-reaching importance. Apart from this living issue, which is now in process of argument and investigation, it is interesting to review briefly the origin of railroads in America.

In this connection Mr. W. P. Maher, writing in "Railway and Locomotive Engineering," has presented a few statistics and data concerning the origin of railroads in the United States, as given below:

The first railroad constructed in the United States was the Quincy railroad (1826). It was three miles in length and was built to transport granite from the quarry at Quincy to the Neponset River, close to Boston harbor. This railroad was laid upon granite ties eight feet apart. The cars were drawn by horses and the usual load was ten tons. The schedule of this railroad was three miles an hour.

The Baltimore & Ohio Railroad is credited with being the first railroad constructed in the United States operated as "a steam railroad." This is erroneous. As a matter of fact the first railroad planned and constructed in the United States to have for its motive power steam engines was the Charleston & Hamburg Railroad, in the State of South Carolina, connecting the port of Charleston, S.C., with the town of Hamburg, S.C., located on the Savannah River, opposite Augusta, Ga., the distance between Charleston and Hamburg being 136 miles.

On December 6, 1827, the city council of Charleston called a public meeting of citizens. After varied discussion towards the means and ends of constructing a line of railway to run from Charleston to Hamburg, on December 19, the legislature passed an act, chartering the South Carolina Canal and Railroad Company. The directors realized the great importance of employing an engineer having special ability in construction work. They began to look around for a suitable person and engaged the services of Horatio Allen. He immediately proceeded to acquaint himself with the details of affairs as they existed and in two months he presented a report to the company embodying the cost of transportation by horse power and by locomotive power.

In March, 1830, E. L. Miller, a native of Charleston, who had been present at the opening of the Liverpool & Manchester Railroad and who had studied closely Stephenson's engine on that line, offered to construct a locomotive after his own plan. The offer was accepted and Mr. Miller proceeded to West Point, N.Y., and built the engine at the West Point foundry. The engine arrived at Charleston the latter part of October and was placed on the road November 2. It was named "The Best Friend." It made its trial trips December 14 and 15, 1830. In speed and power it exceeded the most sanguine expectations. It pulled six cars with 50 passengers at the rate of 20 miles per hour and with the empty cars it made from 30 to 35 miles an hour.

The engine was regularly used in carrying materials over the line, and also was used in between times to carry excursion parties. "The Best Friend" was the first American built locomotive and the road upon which it ran was the first American railroad to employ steam locomotive power. The engineer who had the honor to operate it was a native of Charleston named Nicholas W. Darrell. Through the carelessness, or perhaps due more to inexperience, the negro fireman gave the engine an overdose of steam and on June 17, 1831, "The Best Friend" exploded.

About this time the chief engineer, Allen, designed an eight-wheel locomotive which he had constructed at the West Point foundry. This locomotive was put on the line in January, 1832. It was named "South Carolina." It was a very powerful machine, and was the first eight-wheel locomotive in the world.

On November 7, 1832, the road was completed and opened for traffic between Charleston and Branchville, a distance of 61 miles. On November 2, 1833, the entire line from Charleston to Hamburg was finished and begun its operations of common carrier. It was the longest line of railroad in the world to be operated solely by steam locomotive power.

In summarizing some of the distinctive features of priority that the Charleston & Hamburg Railroad can claim over its competitors, it may be mentioned: It was the first railroad constructed in the United States, built and planned to be operated by steam locomotive power. Constructing and operating on its road the first American-built locomotive. Having for its first chief engineer the man who ran the first locomotive in America.

We learn that in February, 1835, the splendid locomotive "Edgefield" was making its regular schedule, pulling five passenger cars the distance of 136 miles in seven hours and 20 minutes; that the railroad owned 12 engines, 20 passenger cars and 135 freight cars, and that regular schedules were operated—both freight and passenger, and that depots had been built along the line about 10 to 15 miles apart.

This is, in brief, a historical summary of the first steam railroad built in the United States. This line is now a part of the Southern Railway system.

NOTABLE ITALIAN WATER SUPPLY.

With the completion of the Croce di Monaco tunnel through the Eastern Apennines, which was accomplished recently, the last engineering difficulty in the way of finishing the Pugliese aqueduct has been removed. This aqueduct, which was begun in October, 1899, and will, it is hoped, be completed this autumn, is said to be the greatest hydraulic work of its kind ever undertaken.

By diverting the River Sele, which at present flows into the Tyrrhenian Sea below the Gulf of Naples, its waters are carried through the main range of the Apennines to the Adriatic coast of Italy and delivered to the three arid provinces of Puglia. The aqueduct begins at Caposele, 1,358 feet above sea level, and the main waterway running to the eastern slope of the mountains at Venosa is 132½ miles long, of which 60 miles are cut through the rocky mountains.

At Venosa the supply is divided into three, one branch running to Foggia, another to Bari, and the third to Lecce, in the very heel of Italy. These three main conduits have a total length of 1,000 miles. The distribution among the principal towns and communes has necessitated the laying of 500 miles of piping. One hundred and fifty-two reservoirs, each containing 150,000 cubic metres of water, have been constructed at various points. Two and a-half million people will be benefited by the scheme, and 84,000 small land owners will obtain water for the irrigation of their holdings.

The total cost of the undertaking, which has employed 10,000 for 15 years, has exceeded £6,000,000.

Pine and fir piles that have been in service for 43 years in a railway trestle in Great Salt Lake have, upon inspection, been found perfectly sound, due to thorough impregnation with salt.

The Province of British Columbia has an area of 305,000 sq. mi. and a coast line of 7,000 mi. It has 15,000,000 acres of standing timber. There were 2,250 mi. of railway in operation last year, with 2,304 mi. under construction.

WATER STERILIZATION BY ULTRA-VIOLET RAYS.

A PAPER which is being presented by M. von Recklinghausen at the 31st annual convention of the American Institute of Electrical Engineers in Detroit on June 26th, is based upon the sterilization of water by ultra-violet rays of the mercury-vapor quartz lamp. It refers to the historical development of mercury lamp water sterilizers and the development of pistol lamps for large sterilizing units. The sterilization of water is a field that has developed for the application of electricity during the past five years. The experimental work has been done chiefly in France and with it M. von Recklinghausen has been prominently identified. His paper deals particularly with the work done by him in collaboration with Messrs. Henri and Helbonner at the physiological laboratory of the Sorbonne University. A considerable portion of it is devoted to a study of the economical use of ultra-violet rays for this purpose and the best temperature to be employed in the luminous part of the lamp. The measurement of ultra-violet power, based on physical, chemical and bacteriological reactions is explained and these reactions are compared.

It is found best to choose as a unit some value of the particular effect of the rays which concerns the work in hand, and of the four different methods of examining the power of the ultra-violet spectrum the bactericidal or abiotic action is found well suited in the sterilization of water. However, in choosing a unit of bactericidal reaction it was found that cultures of microbes vary so much with age and other conditions that it was impossible to get sufficiently constant results upon which to base a unit reaction. It has been necessary, therefore, to determine the sensibility of the reactive material; i.e., the germ culture on hand, by exposing samples of it to the light of a lamp which has been standardized. This has led to the creation of a laboratory standard lamp to be operated so that it will always produce the same amount of ultra-violet rays. The experimental method of procedure consisted in taking a drop of the culture, exposing it at a definite distance from the lamp, counting the seconds necessary to render them motionless and comparing the

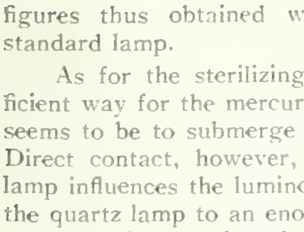

Fig. 1.

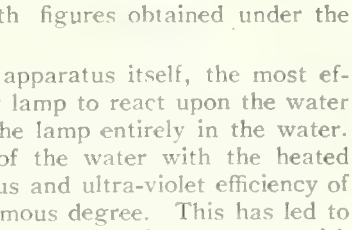

Fig. 2.

figures thus obtained with figures obtained under the standard lamp.

As for the sterilizing apparatus itself, the most efficient way for the mercury lamp to react upon the water seems to be to submerge the lamp entirely in the water. Direct contact, however, of the water with the heated lamp influences the luminous and ultra-violet efficiency of the quartz lamp to an enormous degree. This has led to a means of protecting the lamp from direct contact with the water by fusing over the former a wide quartz jacket. This system has been adopted with modern apparatus. Difficulties arose in the manufacture of such jacketed lamps, however, resulting in the construction of what are known as pistol lamps. Another method is to let the water circulate in such a way around the lamp that it will not come into contact with it, receiving, nevertheless, all the rays emitted by it. Again, where it is more a question of convenience and less a question of efficiency the simplest method is to place the lamp above the water as close as possible to its surface, but reflectors placed above such lamps have a low efficiency in the reflection of ultra-violet rays.

Water bacteria are killed in as short a time as 1/20th of a second at a distance of 1 to 2 centimeters from the powerful ultra-violet ray lamps. Water being practically as transparent to the rays as air itself, if a germ floats in the water it will be annihilated by getting into the illuminated zone, the condition for this being that no suspended matter is contained in the water which would form a shield for the germ.

Water for this sterilization has, therefore, in most cases to be filtered before being submitted to the sterilizing action of the rays. However, even very good filters will allow some microscopic matter to pass. It is much more effective, as shown by experiments, to stir up such water while it is going through the illuminated zone so as to turn over and over any particles which otherwise might allow microbes to pass by under cover. Baffle arrangements are built in for this purpose of stirring up the water. For the same reason, also, it is best to pass the water through several illuminating zones, which can easily be done by leading the water several times towards the same source of light, or by passing it successively under several sources of light.

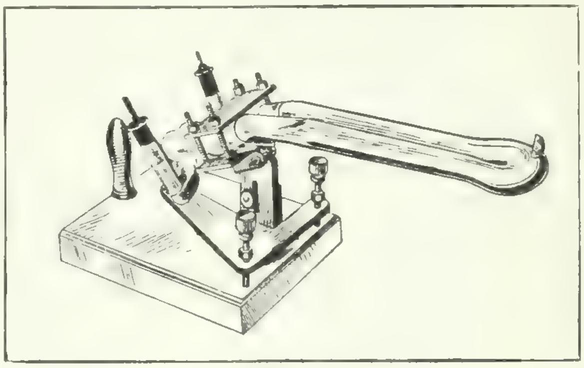

Fig. 3.

Typical Installations.—The largest unit ever built was set up about two years ago in the city of Luneville, France, to sterilize the city water supply. It consists of a flume into the sides of which ten 500-volt pistol lamp equipments are inserted. These equipments consist of metal boxes for the starting of the lamps (the latest types of them contain also the rheostats). The boxes are equipped on the inside with a stuffing box arrangement holding the quartz protective tube which protrudes into the water. The lamps are lit in the starting boxes and then their luminous parts are inserted into the protective tubes, so that the light emitted from the lamp enters the water.

The raw water fed into this plant comes from the Meurthe River and contains sometimes as high as 60,000 germs per cu. cm. It is clarified by a series of roughing filters and one filter. After this it is physically in fairly good condition, being very poor in suspended matter, but having from time to time fairly deep color (up to 45 U.S. standard) in solution. The germ contents are sometimes as high as 1,000 per cu. cm. in this water. It is then passed through the sterilizing unit described above, coming under the influence of the light from one to two minutes altogether, according to the number of lamps running. This number (sometimes only 4) depends on the

physical condition of the water, which is easily observed. The bacteriological tests of the water when leaving the sterilizer rarely show more than 10 germs per cu. cm., and are often zero. Bacterium coli is always eliminated. Not only are the bacteriological tests satisfactory; the health of the community has improved considerably. Typhoid used to cause from 70 to 160 deaths annually; it is now practically eliminated, there being no cases at all this year.

Another typical installation was made in New York lately for the purification of the water of a swimming pool, which is naturally exposed to continuous pollution from the bathers. The water in this case is circulated continually through a filter to take out suspended matter and then it passes through the ultra-violet ray sterilizer. This apparatus is similar to the Luneville unit except for its size, as it contains only two 220-volt pistol lamps. It is rated at 175,000 gallons capacity per day. Tests at the outlet of the sterilizer show only a few germs, and tests of the water going to the purifying apparatus have improved from 6,000 germs per cu. cm. to about 350 germs per cu. cm. since the introduction of the ultra-violet ray apparatus.

Consumption of Electric Energy.—The smallest lamp used in the above apparatus operates at 110 volts with two amperes. The largest made so far is for 500 volts, 2.5 amperes. The largest apparatus built contains ten of the last-mentioned lamps. The power consumption in such a case, with a very large safety coefficient for the sterilization, is between 50 and 130 kw.-hr. per million gallons of water. This amount of power is evidently not very great but it will always do something to smooth out the load curve of a power station, as, in most cases, such apparatus will be operated continuously. Many installations of this kind have been made in Europe for both small and large waterworks, and they are operating very successfully. Their simplicity and rapidity of action are highly satisfactory.

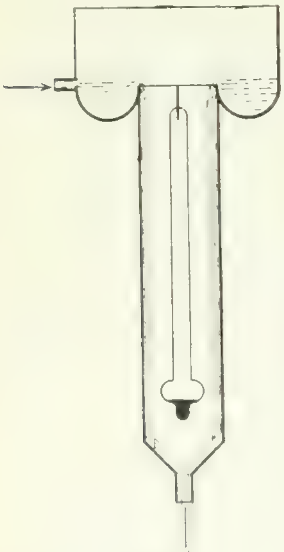

Fig. 4.

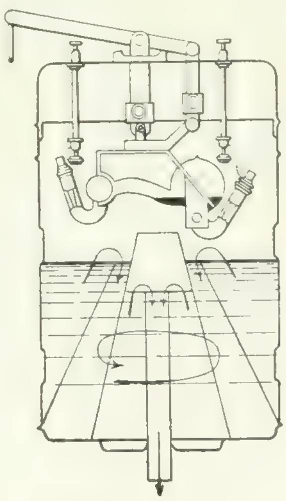

Fig. 5.

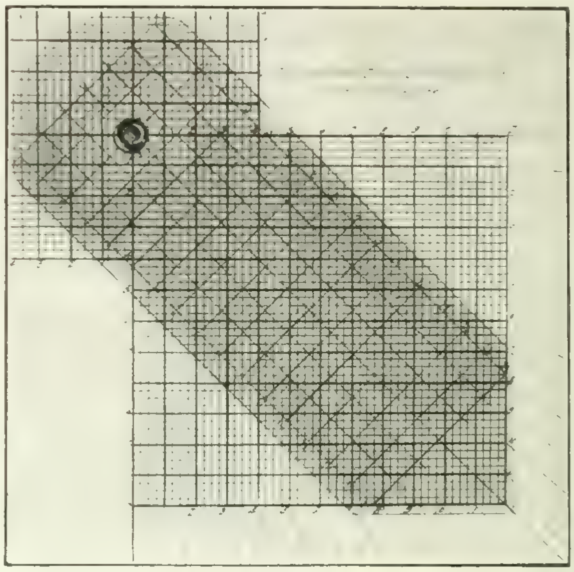
The accompanying illustrations from M. von Recklinghausen's paper, convey an idea of the nature of the apparatus and its use. Fig. 1 shows the entirely submerged lamp used in the experiments of Courmont and Nogier, and Fig. 2 shows the position of the quartz jacket used to prevent contact of water with the light-giving portion of the lamp. Fig. 3 is an illustration of the so-called pistol lamp, which allows all the light to enter the water, at the same time providing a removable lamp. Figs. 4 and 5 show several methods of circulating the water so as to be thoroughly penetrated by the ultra-violet rays, although not coming into contact with the lamp.

NEW BEVEL JOINT DETAILER.

A useful and ingenious little instrument for the detailing of bevelled joints in structural steel work has been designed by W. J. Donley and B. H. Williamson of the Canadian Allis-Chalmers, Limited, Toronto. It is extremely simple in operation, promises to be a great time saver and is at the same time very accurate. It does away with the necessity of making detail layouts to a great extent and has a large field of usefulness to both checkers and detailers.



The accompanying illustration gives a fair idea of the general appearance of the device. It is called the Lightning bevel joint detailer. It is 9 in. square and consists of a back of white celluloid and a movable arm of transparent celluloid, both of which are graduated to half-size scale. The instrument has been thoroughly tried out on the detailing of truss member joints, lateral and partial connections and various other classes of work. It has been found so satisfactory in every case that patents will be applied for and the instrument put on the market.

The Ontario Railway and Municipal Board appointed some little time ago a board of experts to investigate the traffic conditions in Toronto with regard to the street railway system and to make some recommendations for the improvement of the same. A report has been submitted recommending improvement to the extent of an estimated expenditure of $2,950,000. Of this amount $2,160,000 covers additional cars, 180 2-car trains being recommended; $250,000 pertains to track extensions and specials, and $540,000 includes power machinery transmission equipment. The report will be considered at an early date by the Board and the Toronto Railway Co. jointly.

The contract was recently awarded to Messrs. Naylor Bros., of Victoria, for a reinforced concrete bridge of the trestle type to span a ravine about 280 ft. in width and 75 ft. in depth over McCartney Creek, B.C. The new bridge will be located about 4 miles east of the city of North Vancouver, on the Keith Road, which is forming part of the Marine Drive trunk road scheme for the north shore of Burrard Inlet, inaugurated by the District Council in 1911. The bridge will have a 24-ft. roadway, with provision for sidewalks, water mains, etc. The contractors' price was $17,800. The work is well in hand, and the date set forth for completion is July 22nd. It is being built for the Corporation of North Vancouver.

THE FRENCH SYSTEM OF ROAD MAINTENANCE.

At the recent Good Roads Congress in Montreal and elsewhere frequent references have been made to the systematic organization of forces which has attended the construction and maintenance of roads in France. The superiority and completeness of the French road system has world-wide recognition. The technical and administrative organizations in charge of road development in that country are looked upon throughout America as being of the most efficient, and it is generally maintained that such is an evidence of the advantages arising from a systematic organization properly trained and properly equipped for such work.

This French road system was described by Mr. Jean de Pulligny, chief engineer, bridges and roads, and director of the "Mission Francaise d'Ingenieurs aux Etats-Unis," New York City, in a discussion on road construction and maintenance before the American Society of Civil Engineers last year, and appearing in the Proceedings of the Society for September, 1913. From it the following synopsis is given:

The national main highways which connect Paris with the large cities and the frontiers are constructed and maintained by the central government. These main highways (Routes Nationales) were built more than 100 years ago, when scarcely any roads were to be found in other countries, for military purposes and for carrying the royal mail. Their total length is about 24,000 miles, and the annual appropriation for their reconstruction and maintenance is $6,500,000. Since the completion of railways the national main highways are not considered as having as much importance as the other roads of the country, which amount to 339,500 miles in length, and require an annual expenditure of $37,400,000. These roads include mainly Chemins Vicinaux de Grande Communication, connecting the cities and villages, and the less important Chemins Vicinaux Ordinaires, which connect farms with the next village or the nearest city. The Chemins Ruraux are roads connecting one farm with another or connecting farms with more important roads.

Technical Organization.—France, which has a gross area of 207,000 square miles, is divided into 86 territorial units called Departments, having an average area of about 24,000 square miles. The 86 Departments (plus Belfort territory) are divided into 275 Arrondissements and the 275 Arrondissements are composed of 2,325 Cantons, which are divided into 36,222 Communes. Each Department is a political unit, and is a unit for several public services. It has a governor appointed by the central government, called a Prefet, and an elective body called the Conseil Général. It has also certain revenues produced by taxes, the appropriation of which is decided by the Conseil Général.

All the road system of Chemins Vicinaux is managed by the Prefet, and the expenditure is voted by the Conseil Général, the central government having practically nothing to do with it. The Prefet, of course, does not manage the road system himself, but through a centralized body of competent technical men. In about half the Departments the work has been entrusted by the Conseils Généraux to the body of government engineers—Ingenieurs des Ponts et Chaussées—to which the writer has the honor to belong. These roads comprise only a small part of their work. They also have in charge the national main highways and the various civil engineering works which are administered by the French government, including all the inland navigation works, canals and canalized rivers, all the ports, docks, harbors, sea shores and lighthouses, and the close inspection maintained by the French government over the railroads, with reference to safety, regularity and rates, and also to secure a proper maintenance of the railroad property which is only entrusted to the railroad companies for a definite period, at the expiration of which such property will be returned to the government.

In the other half of the Departments (exactly forty-six) special technical bodies have been organized, which are, of course, quite outside of politics. They include a chief road engineer, residing at the capital of the Department, near the Prefet, and having charge of all the Chemins Vicinaux of the Department.

Each Department is divided into three or four political districts headed by a Sous Prefet, and called an Arrondissement. In each capital of each district there resides a district road engineer, who is under the orders of the chief road engineer and has charge of all the Chemins Vicinaux of the Arrondissement.

Each Arrondissement is divided into eight or nine judicial districts, named Cantons, each of which also has its small capital, in which resides an assistant road engineer who has charge of all Chemins Vicinaux included in the Canton. He is under the orders of the district road engineer. Finally, all roads in a Canton are divided into sections, each having an average length of 4 miles, and on each of these sections the celebrated French Cantonnier, or road patrolman, works constantly with his pickaxe, shovel, shrub and wheelbarrow. These Cantonniers are under the orders of the assistant road engineer. A few of them have shorter sections and they look after the work of their neighbors, as foremen (Chefs Cantonniers). The Cantonniers are simple laborers, generally of agricultural training, and are not required to have any special knowledge in order to enter the service. They are only expected to be of respectable behavior, to be able to read and write, and to be steady and trustworthy workers.

It is evident that every square yard of French roads is under the permanent care of a patrolman, of a chief patrolman, of an assistant road engineer, of a district road engineer, and of a chief road engineer. All these men form a hierarchy, with a Prefet as the head. Any complaint by the people, or their representatives, to the Prefet is properly attended to. All members of the road service, from the patrolman to the chief engineer, work under a civil service law. When they have once entered the service they can only be dismissed in case of serious misbehavior. They are promoted at regular intervals, with better pay, and when they retire, after thirty years' work, they get an old age pension. Most of the patrolmen lack sufficient knowledge to become assistant engineers. The latter are recruited by public competitive examinations, taking place every two or three years, from among young men who have studied, by themselves or in school, the necessary subjects, such as the elements of mathematics, surveying, drafting, designing, and road construction and maintenance. The boys employed as helpers for drafting, designing and surveying in the offices of road engineers also generally undergo these public examinations. Their practical experience serves them well, and most of them succeed. The district engineers are generally chosen from among the most able and experienced of the assistant engineers who have had many years of service. The chief engineer for the whole Department may have been previously a district engineer, but it is not obligatory. In some cases he was formerly a civil engineer, a graduate from one of the principal schools, an architect, or an Ingenieur des Ponts et Chaussées.

Table I. shows the number of chief, district and assistant road engineers in each of the 46 Departments where a special road service has been organized.

Salaries.—As examples, statements will be given concerning the salaries of the road engineers and assistants in two Departments: In Seine-et-Marne (population = 358,325; area = 2,300 sq. mi.) the service is entrusted to the Ingenieurs des Ponts et Chaussées; in Seine-et-Oise (population = 707,325; area = 2,170 sq. mi.) there is a special service of departmental road engineers.

Department of Seine-et-Marne (Road Service Entrusted to the Government Civil Engineers).—The body of government civil engineers (Ponts et Chaussées) was created on February 1st, 1716, and the Ecole des Ponts et Chaussées, for the education of such engineers, was founded in 1750.

The classes and salaries in the body of the Ponts et Chaussées are as follows:—

	Annual salary, according to seniority.
Inspecteur Général	$2,900 to $3,400
Ingénieur en Chef	1,900 to 2,300
Ingénieur Ordinaire	965 to 1,350

In addition to their government work, these engineers are allowed to work for departments, cities, chambers of commerce, etc. From this and from other supplements given by the state itself nearly all engineers earn at least $200 yearly. Many earn more, and the supplements of a few equal or exceed their salary.

The state salaries of their assistants are as follows:

Conducteurs (assistant engineers), $425 to $965 per annum, according to seniority.

Commis (office and field graduate assistants), $280 to $675 per annum, according to seniority.

After 30 years of employment, all engineers and assistants are granted an old-age pension of about one-half of the highest salary they have obtained. Besides their state salary and supplements, the engineers and their assistants receive the following fees for their department road service:

Ponts et Chaussées:	Annual fee.
Chief engineer	$1,150
District engineer	575
	According to seniority.
Conducteurs (assistant engineers)	$123 to $192
Office assistants: Head clerks	210 to 385
Typewriters and field and office assistants	50 to 150

The patrolmen are special for the departmental road service. Their monthly salary is as follows, according to seniority:

Chief patrolman	$25 to $27
Patrolman	19 to 21

When these officials are ordered to travel outside the limits of the city in which they reside they receive traveling expenses.

During 1912 the total salaries, traveling and sundry expenses for the road officials, including patrolmen, in the Department of Seine-et-Marne, amounted to $28,000.

Department of Seine-et-Oise (Special Departmental Road Service).—The salaries and old-age pensions after 30 years' service are as follows:

	Annual salary.			Annual pension after 30 years' service.
Agent voyer en chef (chief road engineer)			$1,920	$1,440
District engineer	$960	to	1,100	825
Assistant engineer	480	to	850	640
Office and field graduate assistants	280	to	575	430
	Monthly salary.			
Chief patrolman	$22	to	$25	$121
Patrolman	16.50	to	19	100

Many employees also receive various supplements for the high cost of living in certain cities, help to large families, extra work, traveling expenses, etc.

The total of these expenses for the office staff in the Department during 1911 was $10,400. The total expense for patrolmen and chief patrolmen, including all sundry expenses, was $72,500.

These two Departments are near Paris, where the cost of living and all salaries are high. In many other Departments, the salaries would be smaller by 10 per cent., and, in a few, by 25 per cent.

The total expense for the Chemins Vicinaux of all classes during 1910 amounted to $37,500,000, as follows:

Regular maintenance	$26,355,000
General repairs	2,100,000
Building new roads	4,420,000
Land acquisitions	890,000
Sundry expenses	335,000
Salaries and general expenses	3,400,000
Total	$37,500,000

Administration and Financial Organization.—The engineers of the road service not only build new roads and maintain existing ones, but take an important part in the administrative and financial working of the road system.

The assistant engineers walk nearly all day on the roads of their district, or they may ride on a bicycle, in a carriage, or in an automobile. They constantly meet the elected mayors of the small towns, and they know all the needs of the people. Knowing also approximately the available resources for the coming year, they prepare for each township and for each road of their district a scheme for maintenance expenses and for the building of new roads. They send their reports to the district engineer who sums them up and makes any changes he deems necessary.

Table II.—Mileage of Chemins Vicinaux.

Condition.	De Grande Commun-ication. Miles.	D'Inter-et Commun. Miles.	Ordin-aires. Miles.	Totals. Miles.
Accepted and regularly maintained	107,000	47,200	178,000	332,200
Under construction	287	302	6,700	7,289
Only designed	970	1,770	53,500	56,240
Total	108,257	49,272	238,200	395,729

All the district engineers forward their reports to the chief engineer, who designs a general scheme for the maintenance and building of new roads in the whole Department. Each town or village has its small elective body, which is called to deliberate on the road work and on the expense in which it is concerned. A bill for this scheme is then discussed by the Department's Legislature in its annual session, and may undergo some changes. The appropriation is finally voted, and the works are then carried out with no more intervention on the part of the political representatives, the road engineers acting only under the authority of the Prefet. The expense is levied on the town or village as a public tax, even if the people do not approve of it.

The Chemins Vicinaux, thus taken care of by the Department, are the Chemins de Grand Communication which connect two or more towns or villages. In such cases it is admitted that the maintenance of the roads must not be entrusted to the townships, because one town might do its share of the work and suffer because the other town would not do the same; therefore, the money is provided by the town taxes, but the direction of the work is assumed by the Department.

The construction of new Chemins de Grande Communication is undertaken by the Department for the same reason, but, in this case, there is an important difference as to the origin of the funds. Instead of providing all the money from municipal revenues, the town only give a part of it, and the remainder is appropriated by the department from its share of certain taxes, the amount of which is divided between the Central State, the department and the towns. The sharing of the expense between the town and the department is provided in accord with definite rules, in which both the needs of the township and its resources are considered.

The total revenue produced by certain taxes is supposed to be an index of the comparative wealth of the townships, and the area of their district is considered as a measure of their needs for roads. The revenue being divided by the area, the quotient is considered as an index number by which the townships are classified, and, for a certain index number, they may receive a definite percentage of help from the department, as high as 85 per cent. for a very poor township with a very wide area needing very long roads.

A similar classification is made in the Departments on the same double basis of wealth and area, and an annual appropriation from the Central Government's fund is divided between the departments as a National aid for the construction of their roads. This appropriation amounted to only $2,000,000 in 1910. It has been larger in certain other years.

Such is the technical, administrative, and financial system, and it has worked satisfactorily in France for nearly a century. It only applies to the Chemins Vicinaux de Grande Communication which concern two or more towns or villages.

As for the Chemins Vicinaux Ordinaries, Chemins Ruraux, and Rues (streets) which concern only one town or village, the mayors are free to build and maintain these roads out of the municipal funds, as they wish. In fact, all the villages and small towns voluntarily entrust their road work to the assistant road engineer whom they see daily, and he does it for a small fee. If a town is more important, and if it has a few municipal works of sewerage, water, gas, or electricity, to be looked after besides the road work, a special engineer is appointed who takes care of the whole. If a city is still more important, one or more municipal engineering services are organized. The municipal engineering services of the city of Paris are extremely complete, and their organization is most remarkable, from every point of view.

A few words may be devoted to two other divisions made by the laws of the past in reference to the French roads, namely, the Routes Departmentales and the Chemins d'Interet Commun, which are nothing more than types of Chemins de Grande Communication.

The difference in names carries a few changes in the rules governing the management of these roads and the corresponding funds. These changes are not direct toward simplicity. For many years the tendency in all departments has been to have only one class of roads, the Chemins de Grande Communication. No more Chemins d'Interet Commun are created, and every year some Routes Departmentales are dropped from the official lists, and are afterward considered as Chemins de Grande Communication. The length of the Routes Departmentales has decreased from 29,500 miles, in 1869, to 8,100 at the present time.

On January 1st, 1911, the 395,729 miles of Chemins Vicinaux were distributed as shown in Table II.

As previously stated, there are also 8,100 miles of Routes Departmentales and 24,000 miles of Routes Nationales, forming a grand total of 428,000 miles of roads of all classes.

The building and maintenance expenses of the Chemins Vicinaux have varied according to time and place, but the figures in Table III. give an idea of what

they usually cost. The lengths considered include only the roads accepted or under construction.

For comparison the figures relating to the Routes Nationales have been reproduced, and also some for the Routes Departmentales.

The total length of French roads is nearly 372,000 miles, and their total cost may be considered roughly as more than $1,500,000,000. The difference between these 372,000 miles and the total of 428,000 previously given, results from the omission from Table III. of the 56,240 miles which have only been designed. There are also about 155,000 miles of farm roads, with or without ditches, metaled roadway, and maintenance.

The annual maintenance of the 372,000 miles of regular roads requires nearly $45,500,000, the share of the Central Government being $6,500,000 and that of the 86 Departments nearly $39,000,000. This shows a contribution of about one dollar per head of population.

Table III.—Usual Cost of French Roads.

		Av. Width, in yards		Approximate cost of :— Building.			Annual maintenance.		
Classes	Total length, in miles.	Ditches included.	Ditches excluded.	Total expense.	Per mile	Per square yard, ditches included.	Total expense.	Per mile.	Per square yard, ditches excluded.
Routes Nationales	23,800	20	15½	$ 300,000,000	$12,600	$0.36	$ 6,500,000	$270	$0.0099

Ordinaires	184,700	9	6½	457,000,000	2,470	0.16	14,500,000	78	0.0068
Totals	371,700	....	....	$1,663,000,000	....	....	$45,400,000	....	......

PRIME MOVERS.

In the proceedings of the American Institute of Electrical Engineers appears a paper, entitled "The Present Status of Prime Movers," to be read on June 25th at the 31st annual convention of the Institute in Detroit. This paper, by H. G. Stott, R. J. S. Pigott and W. S. Gorsuch, deals with the present status of heat engines and hydrographic turbines in commercial use at the present time for the conversion of the energy found in fuel and water into mechanical power for the production of electric energy. The paper compares the various types as to relative importance, capacity, efficiency, weight, cost and economy. The prime movers are divided as follows: (1) reciprocating steam engine, (2) steam turbine, (3) gas engine, (4) oil engine, (5) hydrographic turbine. Each is dealt with separately and illustrated by curves showing the above characteristics. At the conclusion of the paper a section devoted to finance and economics also contains a number of curves, which show the investment and fuel costs of the different heat engine units, on the basis of percentage of normal full-load rating of machines.

FIRE DAMAGE TO STEEL BRIDGES.

Serious damage to several steel viaducts in the lumber district of Cleveland, Ohio, was due to a fire which swept over approximately 15 acres, destroying about 15,000,000 ft. of lumber. These two viaducts, in their condition as a result of the conflagration, have provided a subject of interesting discussion for engineers. One of them, the Central Viaduct, built for the city in 1887-88, is 2,835 ft. in length, and consists of pin-connected Pratt deck trusses, with a through steel truss river span. Under it ran a railway viaduct, built in 1905-06. It is about 3,000 ft. long, and consists of a roller lift, a through plate-girder, and several deck plate-girders.

As a result of the fire about 500 ft. of the latter viaduct was seriously affected. The foundation piers were badly disintegrated and many of the steel members distorted and buckled, although no part of it fell.

The Central Viaduct received more serious injury, in that about 270 ft. of it at a point where it was approximately 90 ft. above the ground, broke away and fell across the railway viaduct.

The Waterworks Department of the City of London, Ont., has a total of 2,115 water meters now in use, 451 of which were installed during 1913 and 376 in 1912.

The city of Toronto will shortly submit to its ratepayers a by-law to permit the acquiring of $300,000 for the purpose of purchasing motor buses to serve outlying districts. Full and detailed information regarding the proposal is now being prepared prior to placing the matter before the people.

The new Lake Shore line of the C.P.R. will be in readiness for passenger traffic on June 29. A freight business is being tentatively carried on. This new line will give practically a new route between Montreal and Toronto, and will greatly facilitate in handling the traffic, passenger and freight, which passes through this territory. The work was commenced about two years ago, and entailed a cost of nearly twelve millions of dollars.

A report from New York shows that the unfilled tonnage of the United States Steel Corporation on May 31 totalled 3,998,160 tons, a decrease of 278,908 tons over April.

The Pitt Meadows Oil Company, Vancouver, B.C., whose properties are about 25 miles from Vancouver, has secured oil leases on land in that district totalling 1,920 acres, and has also taken over a well formerly owned by a Vancouver syndicate, comprising, among others, W. I. Paterson, Dr. Robert Telford and T. F. Paterson.

The city of Calgary has under construction this year about 150,000 sq. yds. of asphaltic concrete pavement, about 3,000 sq. yds. of stone block, and about 800 sq. yds. of vitrified brick. These figures are in addition to those which were published in *The Canadian Engineer* for May 21st, 1914, which issue contained a summary of the present season's paving work throughout Canada.

Editorial

GRADE SEPARATION IN HAMILTON.

As a result of the recent decision of the Supreme Court that the Board of Railway Commissioners had not the power by virtue of the Railway Act to order the Toronto, Hamilton and Buffalo Railway to unite with the Grand Trunk Railway and the proposed Canadian Northern Railway to use a common right-of-way and union station in the city of Hamilton, the question of grade separation at once presents itself.

For several years an agitation has been on foot in Hamilton against the present location of the T. H. & B. in the southern and residential section of the city. A common right-of-way scheme was presented to the railways by the city, the G.T.R. and C.N.R. signifying their willingness to consider it, but the T. H. & B. refusing to do so. Then the city went ahead with the preparation of plans and estimates for diverting the latter's track, and applied to the Railway Commission for an order. The question as to whether the Board had power to order the T. H. & B. to remove its tracks from Hunter Street, was subsequently taken to the Supreme Court for a decision. According to it, the Board of Railway Commissioners has not the power, on an application from the city, to make an order directing the T. H. & B. to divert its line from its present location to some other location.

Failing in this, matters stand largely as outlined in *The Canadian Engineer* for September 4th, 1913. Doubtless the depression plan will be taken up forthwith. A plan developed by the city, provides for depressing the tracks of the T. H. & B. at an estimated cost of $1,200,000, in addition to $310,000 land damages. Another depression plan, prepared by Westinghouse, Church, Kerr and Company, and submitted by the railway company, entails an estimated cost of $2,940,000, exclusive of land damages. The same company estimates the cost of elevating the tracks at $760,000. In view, however, of the fact that a portion of the present line is already depressed at the western entrance into the city, a depression scheme will, in all probability, be given early consideration.

PRESERVING ENGINEERING LITERATURE.

The value to the engineer of a library of technical information is so universally recognized in all the branches of the profession that none can contest the arguments in favor of the establishment of such by the individual or the organization of which he forms a part. Everyone is aware that accurate information is as essential to the success of engineering work as a compass is to navigation. In its investigation, design and construction, there must be no empiricism or loose approximations. As one writer has said, information is as necessary a tool in engineering enterprises as the mallet and chisel are in the work of an artisan. Besides, through the medium of print one acquires a knowledge of what others are doing and how—as valuable an asset in a profession as in a competitive business.

With the close of the half year, some weekly engineering journals complete another addition to their standardized volumes, and the thought is in order of immediately binding them for preservation and for facilitating reference when occasion requires. The practice of preserving copies for the purpose of having them bound at the end of the half year is one which should be encouraged and its importance emphasized. Requests from readers for back copies to complete volumes are frequent, and it is regrettable that occasionally these requests cannot be complied with owing to the particular issues being out of print. The result is that the volume is either left unbound or bound in an incomplete state. The wisdom of having a place for each journal and of keeping every copy in its place is evident. Now is the time to begin.

It is not the best thing to do to clip articles from journals for the purpose of filing them. While space on the book-shelf may be saved, and articles on like subjects may be kept together in a single file, it is, in the long run, a waste of time, besides destroying the value of the copy itself. In cases of miscellaneous periodicals which contain, only occasionally, articles of value to the engineer, such a procedure may be advisable, but for the regular engineering and technical journals it is an inefficient method.

One cannot foretell whether articles that are thereby being destroyed, will not attain equal or greater value at some future time than those that are being preserved. No one is so proficient in prophecy as to clearly define what should or need not be clipped for future use. One's range of interests is apt to expand or change entirely as time goes on.

Taking it for granted, therefore, that an engineering journal is not to be read like a newspaper and carelessly thrown aside, there are several important points to keep in mind: When the weekly copy arrives, look it over carefully; examine the index page; clip it (and it only), as suggested in our issue of June 4th. Then place the copy with the previous issues, returning it there whenever it is taken from its place and referred to. When July 1st or January 1st comes round, call in the bookbinder.

HIGHWAY ENGINEERING IN GREAT BRITAIN.

With the advent of mechanically propelled traffic, which has multiplied at a great rate in England during the last ten years, and the discovery that such traffic is highly destructive to road surfaces, especially to those made in waterbound macadam, a serious problem has arisen as to what is an economical form of road paving which is suitable for carrying the new form of traffic. For it is admitted by all English road engineers that waterbound macadam is incapable of withstanding heavy motor propelled traffic, while for light motor traffic it is not economical. On rural main roads its life may, however, be extended by sealing the surface against attritive and weather action by coating it with tar or some tar compounds which have been introduced by commercial firms. Each year, therefore, in most highway districts in England the area of waterbound macadam roads which is protected by a surface dressing of tar is extended and—it is safe to prophecy—that within a measurable number of years waterbound macadam will have disappeared from main roads in England.

RUN-OFF FROM SEWERED AREAS.

In May, 1907, the sanitary section of the Boston Society of Civil Engineers appointed a committee to investigate the above subject. The committee submitted a preliminary report early in 1908, designed particularly to describe the apparatus needed for the gauging of rainfall and run-off. This report offered many valuable suggestions for engineers contemplating the establishment of such apparatus. It has been followed by four progress reports bringing out the difficulties of maintaining gauging stations and of properly interpreting the results of gaugings. It has finally transpired that the committee has brought together all of the gaugings which it has been able to secure and has made such interpretation of the results as is practicable. This final report has been published in the June, 1914, Journal of the Society. It is divided into three main parts: methods of measuring precipitation; methods of measuring run-off, and results of measurements of rainfall and run-off, showing relation between precipitation and flow in sewers.

Methods of Measuring Precipitation.—The automatic or recording rain gauge is the only type which is of use in studies of this character, not only because it is essential that records be taken at the time storms occur, whether that be during the night or at other times when observers might not be on duty, but also and especially because it is the rate of rainfall, rather than total quantity, in which we are interested in studies of this kind. This point is so fully recognized that it is not necessary to do more than refer to it at this time.

A point not always recognized in connection with automatic rain gauges is the great importance of a good clock movement which can be closely and accurately regulated. In comparing the records of several rain gauges or the records of rain gauges with those of sewer gauges, the question of time is one of much importance. The correct time of starting a new gauge sheet and of removing the sheet from the gauge should always be distinctly marked upon the chart. With this information available, it may be possible to adjust the error so as to tell moderately closely the time of occurrence of a storm and the time occupied in travel of the storm.

With all commercial rain gauges on the market, the only method of estimating the time is by noting the position of the pen upon the chart. It is seldom possible to estimate the time closer than five minutes, and frequently it is difficult to estimate it closer than fifteen minutes. It is, therefore, a difficult matter to regulate the clock, or to compare the time indicated by two or more gauges. This would be greatly simplified if all gauges of this type were furnished with clock dials and hands, in addition to the ordinary regulator, so that it might be possible to adjust the clock to the correct time and to keep the clocks of several gauges properly synchronized. In large and important works the possibility of electrical operation of the clocks, thus insuring their keeping proper time and being absolutely synchronized, is worthy of consideration.

The report then enumerates and describes the construction and methods of operation of the principal types of automatic rain gauges, including the Fergusson, Draper, Freiz, Queen, Richard, Marvin, Fitzgerald and Hellman.

Measurement of Run-off.—A measurement of the actual volume of storm water run-off in sewers is not usually practicable. Weirs installed in the sewers themselves are objectionable on the score of the head required [illegible] because they cause a retardation of velocity and retention of sediment; it is also difficult to arrange weirs which shall give satisfactory results under wide variations of flow, and frequently with high velocities of approach. Venturi meters are expensive if furnished with recorders, which are indispensible in studies of storm flow; they have an insufficient range for measuring the wide fluctuations which are likely to occur; and as they must usually be set in inverted siphons in order to register properly, their installation in sewers already built involves some difficulties. Current meters for continuously recording the flow of sewage are not ordinarily practicable on account of the foreign material in the sewage, which is likely to clog the meter, or otherwise derange it. As a result, gaugings, so-called, of storm-water flows in sewers, have almost invariably been made by recording the level of the sewage flowing and computing the quantity of flow, using Kutter's formula, usually with an assumed coefficient of roughness. In order to compute the flowing in the sewer from observations of this kind, it is necessary to know the cross-section of the flowing stream, the slope, and the coefficient of roughness. The former can be readily computed from the known or measured cross-section of the sewer, having given the elevation of the surface of the sewage, which is easily obtained from a record of the water level or flow gauge. In most observations of this character, the hydraulic slope has been assumed as parallel to the invert of the sewer, and a coefficient of roughness, *n* in Kutter's formula, has been assumed. In many cases these assumptions have probably been wide of the truth.

With regard to the hydraulic grade, the following comments by W. W. Horner, principal assistant engineer, Sewer Department, St. Louis, in a discussion of a paper by S. A. Greeley, in "Journal of the Western Society of Engineers" for September, 1913, are pertinent:

". . . It has been noted that there are marked differences between the grade of the sewer and the water surface grade. For example, in a 9-ft. sewer for one rain a depth of flow, at one point, of 4½ ft. was observed; 1,000 ft. downstream the depth was less than 4 ft. though several tributaries entered between, while 500 ft. farther downstream, the depth was over 5 ft. Similar variations have been noted in other rains. The sewer is uniform as to grade, size and condition. The most reasonable explanation of these differences is that the flow at the upper and lower gauges is distributed, in the case of the upper gauge, by a curve 200 ft. upstream, and of the lower by a 3-ft. lateral, discharging into the main sewer nearly at right angles, 100 ft. above the gauge. In both cases the velocities would be materially reduced from that computed by Kutter's formula. In another case, a sharp reverse curve and small local obstruction has been found to create a back pressure above of over 10 ft., although the sewer below was only slightly overcharged."

Other observers have had similar experiences. It is, therefore, evident that the use of the grade of the sewer as representing the hydraulic grade may result in serious errors in computing the actual flow in the sewer. It is obvious that correctly to compute this slope two or more water level indicators are necessary, and these must be exactly synchronized so that the true hydraulic slope corresponding to the depth at any time can be properly computed. The use of maximum flow gauges, indicating merely the maximum height reached by the flood wave at any point, for the purpose of determining the hydraulic slope, is not to be commended, although such gauges serve as a valuable check upon the readings of the automatic gauges. The crest of the flood wave progressing

downstream leaves its record on each of these gauges, but it is obvious that the hydraulic slope is not the slope between the highest point reached at one gauge and the highest point reached at the succeeding gauge, since the crest of the flood was not at both of these points at the same time.

Wide errors may also be introduced into the estimate of flow by incorrect assumption of the value of the coefficient. It is only necessary to call attention to the fact that the values of n in Kutter's formula for the classes of sewers ordinarily gauged may range from 0.009 to 0.017 in order to realize that assumptions of this coefficient may be far from the truth. These two values, as it happens, have been found by velocity measurements at Pawtucket and Philadelphia to apply to the particular cases referred to; but it is evident that the assumption of such coefficients without experimental determination may introduce serious errors, possibly as much as 50 per cent. Obviously, this method of estimating flow can only be correctly employed when the coefficient is experimentally determined for the sewer under consideration. Either the coefficient of roughness n in Kutter's formula, or the coefficient C in the Hazen-Williams formula, may be determined and employed in the estimation of flow. It is not thought best to use the Chezy formula directly, since the coefficient in this formula would not be constant for varying depths in the sewer and the resulting changes in the hydraulic radius.

In the study of run-off at Pawtucket the following investigations were made in an endeavor to find the value for n in the Kutter formula for the sewer under investigation. The diameter of the sewer was too small to permit of the use of current meters when measuring storm flows. It is seldom that a depth greater than one foot is reached in this sewer, and most of the observations had to do with much lesser depths.

Because of these conditions, floats were tried between manholes 447 ft. apart. The surface slope of the discharge corresponded with the slope of the sewer, as nearly as it was practical to measure the depth of flow, and the slope of the sewer, .006, was therefore adopted for the value of s.

The floats used were pieces of wood three inches in diameter and two inches long, and the time taken for the passage of these between manholes was recorded by observers. About 170 observations were recorded, during storms occurring between February, 1905, and February, 1906, and from these data ninety-one velocities were figured for various depths of flow between 0.16 and 1.1 ft. These velocities have been plotted and a curve drawn which corresponds very closely to the curve of Kutter's formula when using a value for n of .0085.

As the velocity measured was the surface velocity, and therefore, for the shallow depths observed, was very nearly a maximum, it is fair to assume a somewhat lower figure for the average velocity. Mr. Fteley, in his measurements of the flow in the Sudbury River Conduit, found the average velocity there to be about 88 per cent. of the maximum velocity, and a velocity curve cd, representing 88 per cent. of the observed velocity has been drawn.

This curve lies between the curves of the Kutter formula drawn with values for n of .010 and .009, but very close to the former curve. It is identical with the velocity curve of the Hazen and Williams formula when giving a value of 150 to c in that formula, [illegible] $0.001^{-0.04}$.

With respect to this latter formula, it may be said that c has a range of 145 to 152 when compared with the experiments of Darcy and Bazin in semi-circular conduits of 4.1 ft. diameter, with a surface of pure cement.

The following quotation is taken from W. G. Taylor's description of a new main intercepting sewer at Waterbury, Conn.: "Observations upon the sewage flow in the main carrier, at depths up to the springing line, have shown that the value of n in Kutter's formula when applied to the sewer flow is not greater than 0.010." The sewer for which these values were obtained was of reinforced concrete of horseshoe shape, 5 ft. 6 in. x 4 ft. 5 in. Great care was used in churning the deposited concrete, and the interior and exterior surfaces are reported as being "very smooth."

Types of Recording Gauges.—Leaving Venturi and current meters out of consideration, practically the only type of automatic gauge applicable to gauging storm water flows in sewers is a gauge of the water level recorder type. All of the gauges available for this purpose may be divided into two general classes—float gauges and pneumatic pressure gauges. Either class is equally applicable to keeping a continuous record of the head of water over a weir in case it is practicable to use a weir for accurate measurements of flow.

In order to secure proper registration with any type of gauge, it is practically essential to install the float or pressure chamber in a separate manhole connected with the sewer, rather than in the sewer itself. This adds materially to the cost of installing the gauge and keeping records of sewer flow, but it has not been found practicable to obtain trustworthy records by means of a gauge installed directly in the sewer itself.

In the float gauge a float contained within a pipe or other suitable guide is connected with a recording apparatus through the medium of a cord, chain, tape or by a solid rod or tube.

The report then presents descriptions of various recording gauges including the Hydro-Chronograph, Freiz's improved water stage register, Builders' iron water level register, pneumatic pressure and diaphragm gauges, and Sandborn's flow recorder.

Installation of Automatic Sewer Gauge.—A reliable automatic record of the depth of the storm flow in the sewer is of equal importance with the record of the rate of precipitation, but is even more difficult to obtain. So many difficulties beset the installation of an accessible recording device that it has been very hard to obtain the co-operation of municipal engineers in this work. In sewers less than four feet in diameter and in any sewer where the normal dry-weather flow is of very shallow depth, the installation of a recording device in the sewer itself is apt to produce such an obstruction to the flow as will set up artificial conditions, which make a record of the correct depth of flow impossible.

It is therefore much better to construct an auxiliary manhole, independent of the sewer, for the special purpose of installing the recording mechanism. In this manhole a float chamber can be constructed and connected with the main sewer by a small pipe, or pipes, and these need be the only connection with the sewer. Under such a construction it will be possible to visit and inspect the recording mechanism without the inconvenience attendant upon a descent into a regular manhole which is a part of the sewer itself. It will still have the disagreeable feature, however, of being below ground and accessible only through an opening in the street surface. A much better location for the recording device is at the edge of the curb and above the level of the sidewalk. This can be accomplished through a construction similar to a police

signal box, and the chart will thus be made readily accessible. The only criticism of such a method of installation lies in the necessity of providing some method of accurately checking the chart record with the depth of flow.

Particular care should be taken in connecting the gauging chamber or float chamber with the sewer, to see that the connecting pipe is normal to the direction of flow, and does not project into the sewer. If this precaution is not observed, the recorded heights will be in error—too high if the connecting pipe is directed upstream or against the current, and too low if in the reverse direction. The precautions taken should be the same as in installing a piezometer connection to a water pipe.

It is highly necessary that recording devices be regularly inspected in order that they may be sure to be in operation when most needed, and the more accessible and convenient it is possible to make their location, the more careful attention will they receive. Maximum rates of precipitation and the attendant depth of flow in the sewer are of infrequent occurrence, and it is very essential that the recording device be in operation whenever such a discharge takes place.

Maximum Flow Gauges.—Practically the only information to be obtained from a maximum flow gauge is the greatest height reached by the flood wave at the point of observation since the last recorded measurement. Ordinarily the records thus obtained are of little value, but they may occasionally serve as a valuable check upon the records of an automatic gauge which may be out of order and fail to indicate the highest point reached by the flood. It is, therefore, advisable to install such maximum flow gauges at all points where automatic water level recorders are installed.

In the earlier observations of run-off in sewers, the maximum gauges consisted merely of whitewashed laths set firmly in position in manholes, the expectation being that the highest point reached by the sewage would be clearly indicated on the whitewash. In some cases this simple type of gauge has proven satisfactory, although in many cases the whitewash has peeled off about the height to which the sewage reached, and in other cases, for some unexplained reason, the maximum height could not be distinguished upon the gauge. The most satisfactory type thus far devised consists of a rod to which are firmly fastened a number of small vials having their mouths set at uniform distances apart, usually one-tenth or two-tenths of a foot, the whole being properly protected from the flowing current by a shield or perforated tube. On examining this rod, it is evident that the sewage must have been as high as the highest vial which is found to be filled with water. Inverting the rod and emptying the vials is all that is necessary to prepare the gauge for use. This type of gauge is best located in a manhole, with the bottom of the gauge slightly above the normal dry-weather flow. In some cases, gauges of this type have not proved satisfactory where high velocities have obtained—such as 8 ft. per second.

Actual Measurements of Storm-water Flow.—The report contains, in tabular form, all available records of storm-water flows in sewers, including not only those which have been made in co-operation with the committee and submitted to it for publication, but all other published records of storm sewer gaugings which have come to its attention. It gives also a detailed description of apparatus and methods used in a study of rainfall and run-off at Pawtucket, R.I.

Rate of Precipitation Causing Maximum Flow.—It is of the greatest importance in arriving at a correct conclusion that the maximum rate of flow in the sewer be compared with the rainfall which actually caused this run-off. It is, therefore, particularly important that the time required for concentration of run-off at the gauging point, under the conditions existing at the time when the gauging was made, be accurately known.

It is evident that if the time required for the concentration of the run-off at the gauging point is thirty minutes, the run-off factor obtained by comparing the maximum rate of run-off with the rate of rainfall which obtained for a period of five minutes, or with the average rate which obtained for a period of sixty minutes, would be considerably in error, unless the rate were uniform in the latter case. In such comparisons it is evident that the actual time of concentration existing for the particular gauging is the figure desired—not the computed time of concentration for maximum velocities of flow, which may be widely different from those existing. If the sewers are but partly filled and the velocity of flow is less than the maximum velocity, it is evident that the time of concentration will be considerably greater than the time computed upon the basis of maximum velocities.

Another point requiring careful consideration is the interpretation of the run-off from storms of less total duration, or having a downpour of less total duration, than the time of concentration for the drainage system gauged. This is particularly true in the case of large areas for which the time of concentration is considerable. It is not often that storms occur of sufficient uniform intensity to produce a noticeable "flood wave," and lasting from thirty to sixty or ninety minutes. Accordingly, storms which give significant information relating to drainage areas for which the time of concentration exceeds thirty minutes are of rare occurrence, and records of value for such systems are obtainable only after a number of years of observation. Much valuable information could be obtained in shorter periods of time if sub-districts, for which the time of concentration would be short, were gauged. The committee spent a large amount of time in endeavoring to obtain significant information from storms in which the period of downpour was of less duration than the time of concentration of the district gauged, but had been forced to the conclusion that, with present knowledge, no information of value can be obtained from such records. It seems impossible to estimate the area actually yielding storm water from a shower of less duration than the time of concentration. Take, for instance, the case of a heavy downpour lasting ten minutes upon a drainage area for which the time of concentration is thirty minutes. If the entire rainstorm lasts but ten minutes, it is evident that the maximum rate of run-off represents the discharge from but a portion of the drainage area. Whether this is the portion lying nearest the outlet or some other part of the drainage area, it would be impossible to tell without a very large amount of information. If the storm included a heavy downpour of ten minutes' duration, followed by a drizzle of indefinite duration, the maximum run-off would probably occur when a section of the drainage area at a distance from the gauging point was contributing at the maximum rate, while portions nearer the gauging point were contributing the run-off corresponding to the lighter rainfall which followed the downpour. It is therefore impossible to say what the true contributing drainage area to the maximum run-off amounted to, or what is the proper rate of precipitation with which that run-off should be compared.

The report concluded with a description of the sewer districts gauged, together with data relating to the location and type of rain gauge, method of gauging flow, etc.

The committee expressed itself of the opinion that more will be accomplished by a larger number of gaugings of small drainage areas than by attempts to gauge areas of larger extent. With the smaller drainage areas the time of concentration will be less and there will be a much larger number of storms in which there can be little doubt that the maximum rate of rainfall continued at a uniform rate for a sufficient period to produce the maximum observed run-off, and accordingly, the resulting computed coefficient of run-off will be more nearly correct. In such cases, also, the difference between the computed time of concentration under conditions of maximum velocity through the sewer, and the time of concentration actually existing for any particular observation, will be slight. Moreover, in small districts, the main channels will not be large and the effect upon the results of storage in the sewers themselves will not be great.

It is not intended to minimize the value of careful gaugings of the medium-sized and larger drainage areas. Such measurements are of great value and it is to be hoped that they will be continued. Measurements of discharge from areas of 200 to 500 acres are perhaps likely to be of most general applicability, and should be encouraged whenever it is possible to make an extended series of gaugings. Where, however, the means are seriously limited and the probability of continuing gaugings over a long period is not great, it is believed wiser to carry out measurements upon smaller districts from which results can be obtained in a shorter period of time. It is very much to be desired that measurements of the flow from subdistricts, which together make up a large district, whether or not the entire district is also gauged as a whole, should be undertaken as extensively as possible.

Information relating to inlet time or time required from the beginning of the rain to the moment when the flow is established at the storm water inlet is also of importance, and little or no accurate information is to be had upon this subject.

The personnel of the committee was as follows: George A. Carpenter, chairman; Harrison P. Eddy, secretary; William S. Johnson, Hector J. Hughes, Lewis M. Hastings, Arthur T. Safford, George C. Whipple, Harold K. Barrows.

MONTREAL IRON AND STEEL SITUATION.

In iron and steel circles it is declared that the foundries are not working more than 10 per cent. to 20 per cent. as many hours as they worked formerly. The larger industries, such as the railway shops, car and locomotive works, are almost closed down. The repair shops of one sort and another seem to be about half occupied, and foundries engaged on staple lines—such, for instance, as stoves, furnaces, etc., are apparently working about 75 per cent. of capacity. On the whole, the demand for iron has fallen off to a minimum.

The trade is keeping a close watch on developments on the other side of the line where the steel companies seem to have been meeting a rather better demand lately, and where the orders placed show a considerable increase in volume, although it is understood that this increase was largely the result of a shading in price in the Pittsburg district. Around Buffalo, prices appear to be holding firm.

The opinion in the trade is that little or no improvement is in sight. The only consolation is that consumption is undoubtedly greater than production, and the result must sooner or later be that new supplies will have to be purchased.

Montreal, June 23rd, 1914.

OIL PRODUCTION IN CANADA.

In view of the publicity given to the oil area in the vicinity of Calgary, and the numerous companies formed since the discovery, a partial list of which has been given in recent issues of *The Canadian Engineer*, the following government return is especially interesting.

The production of crude petroleum in Canada was still confined during 1913 to the old established fields in Ontario with a few barrels pumped from gas wells in New Brunswick.

The annual output has been steadily declining during the past six years, and shows a further falling off in quantity produced in 1913, although owing to the higher price obtained for oil a larger total value is shown than for 1912.

A bounty of one and a half cents per imperial gallon is paid upon the production of crude petroleum, the Bounty Act being administered and payments made by the department of trade and commerce. According to the records of this department the total output of petroleum in 1913 was 228,080 barrels or 7,982,798 gallons on which a bounty of $119,741.97 was paid. The total value of the production at the average price for the year $1.782 per barrel was $406,439.

The production in 1912 was 243,336 barrels or 8,516,762 gallons valued at $345,050, or an average value of $1.418 per barrel. The average price per barrel at Petrolia during 1913 increased from a minimum on January 1 of $1.65 to $1.75 on April 16, $1.84 November 6, and $1.89 on December 22.

The production in Ontario as furnished by the supervisor of petroleum bounties was in 1913 as follows in barrels:—Lambton, 155,747; Tilbury, 26,824; Bothwell, 34,349; Dutton, 4,610; Onondaga, 4,172, and Belle River, 464, or a total of 226,166 barrels. In 1912 the production by districts was: Lambton, 150,272; Tilbury, 44,727; Bothwell, 34,486; Dutton, 4,335, and Onondaga, 7,115, or a total of 240,935 barrels.

The production in New Brunswick in 1913 was 2,111 barrels as against 2,679 barrels in 1912 and 2,461 barrels in 1911.

Exports entered as crude mineral oil in 1913 were 3,650 gallons valued at $379 and refined oil 24,273 gallons valued at $3,188. There was also an export of naphtha and gasoline of 17,875 gallons valued at $4,284.

The total value of the imports of petroleum and petroleum products in 1913, states Mr. J. McLeish, in his annual report, amounted to $13,339,326 as against a value of $11,978,053 in 1912. The imports have been increasing rapidly during the past few years.

Crude oil is being extensively used as fuel on the Pacific Coast in both steamships and locomotives, and the wide use of the gasoline motor has created a big demand for gasoline. The total imports of petroleum oils, crude and refined, in 1913 were 222,779,293 gallons, valued at $13,230,429 in addition to 1,628,837 pounds of wax and candles valued at $108,897. The oil imports included crude oil 162,062,201 gallons, valued at $5,250,835; refined and illuminating oils 19,393,627 gallons valued at $1,386,440; gasoline 29,525,170 gallons valued at $4,822,941; lubricating oils 6,789,451 gallons valued at $1,172,986, and other petroleum products 5,008,844 gallons valued at $507,227.

The total imports in 1912 were 186,787,484 gallons of petroleum oils crude and refined valued at $11,858,533 in addition to 2,144,006 pounds of paraffin wax and candles valued at $119,520. The oil imports included: crude oil, 120,082,405 gallons, valued at $3,996,842; refined and illuminating oils, 14,748,218 gallons valued at $1,012,735; gasoline, 40,904,598 gallons valued at $5,347,767; lubricating oils, 6,763,800 gallons valued at $1,077,712, and other petroleum products 4,288,463 gallons valued at $423,477.

There was an increased importation in 1913 of all classes of oil with the exception of gasoline, the increases being most pronounced in crude oil and refined illuminating oil.

There was comparatively little change in the production of natural gas in Ontario, but a large increase in the production in New Brunswick and in Alberta. The total production in 1913 was approximately 20,345 million feet valued at $3,338,314, of which 828 million feet valued at $174,006 was from New Brunswick; 12,487 million feet valued at $2,092,400 from Ontario and 7,030 million feet valued at $1,071,908 from Alberta.

The production in 1912 was reported as 15,287 million feet valued at $2,362,700, and included 174 million feet from New Brunswick valued at $36,540; 12,529 million feet from Ontario valued at $2,036,245 and 2,584 million feet from Alberta valued at $289,906.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

CONTENTS.

BOOK REVIEWS.

Poor's Manual of Public Utilities for 1914.—Published by Poor's Railroad Manual Company, 535 Pearl Street, New York. Second Annual Number. 2172 pages of text; 6 x 9 ins.

This important financial reference work contains 248 pages more than the first edition. About 400 new statements and 300 new comparative tables have been added. Bond descriptions have been amplified, and in the majority of them information is given showing whether or not interest is payable without deduction for the normal United States income tax.

A valuable new feature is the re-arrangement of the street railways. The old arrangement of presenting statements by States has been dropped in order that street railways in public utility systems may appear in connection with the statements of the respective holding companies.

The manual is the only one devoted entirely to the public service corporations. It gives the same service to the public utilities that Poor's Manual of Railroads has given to the railroads for nearly half a century.

The Electric Furnace.—By Alfred Stansfield, D.Sc., Professor of Metallurgy, McGill University. Published by McGraw Hill Book Company, New York. 415 pages, 155 illustrations, 6 x 9 ins.; cloth. Price, $4.00. Reviewed by T. R. Loudon, Assistant Professor of Ferro-Metallurgy, University of Toronto.

This book is an enlargement of the well-known first edition, published in book form in 1907 after portions had appeared as serial articles in *The Canadian Engineer.*

As stated in the introduction, it has been the author's endeavor to trace the evolution of the electric furnace and to set forth the outstanding facts relative to the theory and practice in design and operation of the present-day furnace. The author is to be congratulated on the clearness with which this has been accomplished. The work is, of course, very largely a compilation of theory, the references being quite numerous and varied.

There are fifteen chapters as follows: History, Description and Classification of Electric Furnaces; Efficiency of Electric and other Furnaces and Relative Cost of Electrical and Fuel Heat; Construction and Design; Operation; Laboratory Furnace; Production of Pig Iron; Production of Steel from Metallic Ingredients; Production of Steel from Ore; Ferro Alloys; Graphite and Carbides; Zinc and other Metals; Miscellaneous Uses; Electrolysis and Electrolytic Processes; Future Developments. The above list is abbreviated in some cases.

Chapter IV. on Construction and Design gives a good description of the various refractories used in furnace construction. The description is necessarily brief, but is well written, which is not always the case in most descriptions of refractories. A number of details of construction are given, but in this respect there is rather a lack, the discussion having the appearance of being too theoretical.

The chapter on Operation has also the objection of being theoretical. The term "operation" obviously refers to the practical. Such sections as voltages required for electric furnaces and current density in furnaces would be more in keeping in the chapter on Design.

Chapter VII. deals with the production of pig iron.

A great deal of space is taken up in discussing the results obtained in the Sault Ste. Marie experiments and the European Commission's report. The familiar results of the Swedish furnaces and the furnaces at Herault, California, are also given.

Chapter VIII., dealing with the various forms of steel furnaces, gives descriptions of the well-known types. Chapter IX. discusses the making of steel from iron ore, dwelling at length on experiments carried on by the author himself in the so-called Evans Stansfield furnace. It is worthy of note that the only practical furnace in Canada has been omitted; that is, the Moffatt-Irving furnace, which has been in operation for some time making steel from ore.

The author has gone very thoroughly into the question of zinc smelting.

The book is a valuable compendium of references on articles scattered throughout the technical literature of the day.

Designing and Detailing of Simple Steel Structures.—By Clyde T. Morris, C.E., Professor of Structural Engineering, Ohio State University. Published by McGraw-Hill Book Company, Inc., New York City. Third edition; 260 pages; 94 illustrations; cloth; 6 x 9 ins. Price, $2.25.

This book has been carefully revised and reset, portions of it having been practically re-written since the publication of the first edition in 1909. Those who are familiar with the previous works will note a change in the order of the chapters and an increase in volume. The chapters, as they occur, are as follows: Designing and Estimating; Riveting; Mill Buildings; Plate Girder Bridges; Pin-connected Bridges; Highway Bridges, Manufacture; and an appendix containing the general specifications for steel railway bridges (1911) of Ohio State Highway Department.

The book will be found valuable as an elementary treatise upon design, and students in engineering colleges and technical schools have in it a work adapted to their needs and to the limited time which they generally have in which to refer to the subject. The text contains numerical examples which add materially to the descriptive matter and the carefully-arranged exposition of theory.

The Coöperation of Science and Industry.—By S. Roy Illingworth. Published by Chas. Griffin & Company, Limited, Strand, London, England. 91 pages; 3½ x 5 ins.; leather. Price, 30 cents net.

In this little work Mr. Illingworth has urged a closer relation between industrial establishments and applied science. The problem has been viewed from an impartial standpoint, commencing with the long and tedious period prior to the 18th century, through which the gradual evolution of industrial enterprises experienced comparatively unappreciable change compared with the momentum which the same and similar industries have gained since the development of industrial research in the 18th century. The author refers to the work of the scientist in the cultivation of the by-products of coal as an example of what may be accomplished when applied science is permitted to unite with industry in the promotion of efficiency and of new commercial enterprises.

The Englishman, regarded as the pioneer of industry, is pronounced delinquent and too prone to disregard processes as unremunerative or useless rather than to recognize the value of the application of science thereto. The present industrial position of Germany is presented as an example of the results which might be expected from a judicious intermingling of the two.

Taken altogether, the book presents some forceful arguments in favor of more scientific methods in the establishments of the British manufacturer, and its application should not be considered limited to any country or to any industry.

Engineering Manual.—Published by the American Electric Railway Engineering Association, New York City. Size, 6 x 9 ins.; cloth binder. Price, $3.00; binders, $1.00.

This Engineering Manual for 1914 is a compilation of the standards and recommendations adopted by the Association, and covers practically the entire field of electric engineering. Miscellaneous methods and practices are outlined therein which include, as well, all definitely approved recommendations other than those of the Association itself. It is in the form of a loose-leaf binder, and includes 82 sections, which are fully illustrated with diagrams and working drawings. The Manual, which is free to members of the Association, has been put into loose-leaf form in order that the standards and recommendations may keep pace with such additions and alterations as are made at the yearly conventions of the associations.

The volume possesses a very complete index of the material contained therein, and covers also references to related subjects as to their location in the proceedings of the Association. Being revised each year and containing a complete collection of information of the most practical value to electric railway men, the volume will be found of great use.

The Job, The Man, The Boss.—By Dr. K. H. M. Blackford and Arthur Newcomb. Published by Doubleday, Page & Company, New York, 1914. 226 pages, 23 half-tone illustrations. Price, $1.60. Reviewed by Geo. S. Hodgins, Assistant Engineer (Mechanical Department), National Transcontinental Railway.

In a quite remarkable book dealing with the engaging or hiring of men, the authors show that each man bears about with him in his speech, behavior and actions the indelible record of his tastes, faculties and aptitudes. It is the business of the Employment Bureau, wherever established, in factory, mill, bank or railway repair shop, to view with the trained eye of science each applicant for work; and with what amounts to almost complete knowledge of his past, revealed by his build, his words, his movements and his health, to predict his future actions, and to "fit" him in his place.

With this kind of knowledge, and knowing the requirements of each job, the employment department picks out the best available man and places him where he ought to be, and where he will find his work congenial. Here he will do his best work and please himself and be a source of profit and satisfaction to his employer.

The book is not only a valuable contribution to the whole science of selecting men, but is a practical work that well might be in the hands of any intelligent foreman or gang-boss who handles applicants where the "hire-and-fire" system still prevails. A railway roundhouse, a small machine shop, or even a special laborers' squad, would feel the benefits of the system here outlined.

It is pleasant reading, easily understood, and the matter, once taken in, sticks in the mind for ready reference and for use. The chapters on "Analyzing the Man," beginning with "heredity and environment," are simply fascinating. The "nine physical variables" are defined and explained, how they came into being, what they mean, what they still stand for, and why they are evidence of character and aptitude. This kind of knowledge may easily prevent a boss from shoving a square peg into a round hole

All men bear about in face and frame and gait and word, certain evidences of character. They cannot conceal them if they would, and the majority do not know they have them, but they betray their likes and prejudices, their aptitudes and abilities, in many curious ways, like Achilles, concealed among the daughters of Lycomodes, who, unthinking, stretched forth his hand to grasp the sword as it clanged down upon the floor from amid the costly fabrics, and thus revealed himself to the astute Ulysses, who had brought the gorgeous raiment, ostensibly to charm the maidens, and to gain their father's smile.

The book is written in a kindly, optimistic spirit that looks for the dawn of a brighter day for all. There is no trace of idle dreaming; it is the clear and helpful statement of undoubted scientific fact.

A Treatise on the Inspection of Concrete Construction.—By Jerome Cochran, B.S., C.E., M.C.E. Published by Myron C. Clark Publishing Company, Chicago. 595 pages; 26 illustrations; 6 x 9 ins.; cloth. Price, $4.00. Reviewed by C. S. L. Hertzberg, of James, Loudon and Hertzberg, Consulting Engineers, Toronto.

This book is a very elaborate and comprehensive treatise on all phases of concrete work. It is intended, primarily, for the use of inspectors on concrete construction, but it is a work which will be found very useful to engineers, architects, contractors, and, in fact, anyone who is in any way interested in concrete work.

The introduction deals, at some length, with the necessity of good inspection, and outlines, in a brief way, the duties, necessary qualifications and responsibilities of the inspector, together with a few hints as to the best way of dealing with contractors, etc.

A rather complete treatise on cement and aggregates is given in Chapters I. and II., together with methods of testing and standard requirements.

Chapters III. and IV. deal with the inspection of mixing operations and form work.

In Chapters V., VI. and VII. the inspection of reinforcing steel, pouring of concrete and concrete finishes are fully treated. The remainder of the book deals, in detail, with the inspection of particular types of concrete construction.

It is seldom one meets with a book so thorough in its attention to important details, and the author's complete familiarity with concrete construction in all its numerous forms has resulted in the production of a particularly useful book.

In the chapter on the proportioning of concrete a 1:2:4 mix is referred to (when speaking of the aggregate collectively) as a 1:6 mix. The meaning is made quite clear in the sentence which follows, and there should be no reason for any misinterpretation. However, this method of referring to proportions has led to errors being made when the aggregate was composed of unscreened, pit-run gravel, and a mixture of one of cement to six of gravel has been substituted for the specified 1:2:4 mix. A number of engineers are now referring to the combined aggregate equivalent of a 1:2:4 concrete as a 1:4 concrete.

Engineering Geology.—By Heinrich Ries, Ph.D., and Thos. L. Watson, Professors of Economic Geology in Cornell and Virginia Universities, respectively. Published by John Wiley and Sons, New York (Canadian Selling Agents, Renouf Publishing Company, Montreal). 672 + 26 pages; 400 illustrations; cloth; 6 x 9 ins. Price, $4.00 net. Reviewed by J. Keele, Geological Survey of Canada.

It has long been the opinion of those who have given consideration to the subject, that a course in applied geology is better suited to the needs of students in engineering than a portion of the abstract course in this science for arts students which they usually receive. The limited time at the disposal of the engineering student does not allow of going very far into the study of general geology; hence, as a rule, he is not very much interested in it, and promptly forgets the little he learns at college. It would seem, therefore, that the application of the principles of geology to the problems of engineering might be the best method of securing his attention.

This is the object of Messrs. Ries and Watson in their book, entitled "Engineering Geology." The authors are geologists of wide experience, both in teaching and field work, and, moreover, have given special attention to the part geology has played in all modern engineering achievement. Therefore, they are well qualified to select and put in order those aspects of geology that some time or other will surely enter into the practice of general engineering. Beginning with the common rock-forming minerals which leads to rocks in general and a description of their structural features, we have in the first three chapters as much as any engineer wants to know on these subjects. The importance of certain structural features, such as faulting and folding, with their influence on tunnels, aqueducts or foundations, are emphasized in separate sections. Defects in the earth's crust sometimes have a disagreeable manner of asserting themselves to the unwary engineer.

Four chapters are devoted to the work of water, both above and below the surface of the earth. The relation of wave action and shore currents to coasts and harbors, the destructive and constructive work of stream erosion, the effect of superficial deposits and bed-rock structure upon underground water, and the conditions that lead to pollution of water supply are all very fully explained and illustrated by sections and diagrams. The manner in which the subject of the work of water is presented deserves attention. Physiography is that branch of geology which deals with land forms and the causes, mainly erosional, that produce them. It may be reckoned as a purely cultural subject, like Greek, when regarded from the theoretic point of view. The authors of "Engineering Geology" dispense with an intricate discussion on the genesis of land forms, but by practical applications of the results of the forces at work indicate how these forms were produced.

An important part of the work of modern engineering is concerned with controlling, distributing, and conserving water supplies. Enormous sums of money are spent on these undertakings. Therefore, a thorough knowledge of all the influences that may affect these undertakings is an essential portion of an engineer's equipment.

Although rocks, clays and soils enter largely into the industrial life, and social welfare of our country, intimate knowledge of these materials is rare, and important problems regarding their utilization are still unsolved. The chapter on rock weathering and formation of soils in this volume forms an introduction to the relation between geology and structural materials. These include building stone, limes, cements, plaster, clays and clay products. In addition to a brief account of occurrence of these materials in nature, a surprisingly large amount of the technology of them is condensed within a small compass.

The coal series, petroleum and natural gas, are very fully treated in the space allotted to them. A chapter on the origin, nature and occurrence of the principal metallic ore deposits concludes the volume.

Although this book is written mainly for the use of civil engineers, mining engineers will also find much useful matter in it. It is essentially a work on geology for the technical man.

A list of works of reference at the end of each chapter is a valuable feature of the book. It is also very fully illustrated with half-tone reproductions of photographs, and numerous line drawings of an explanatory nature.

Foundations of Bridges and Buildings.—By Henry S. Jacoby, Professor of Bridge Engineering, Cornell University, and Roland P. Davis, Professor of Structural and Hydraulic Engineering, West Virginia University. New York: McGraw-Hill Book Company, Inc. Cloth; xvi. + 603 pages; 295 text figures and full-page illustrations; 6 x 9 ins. Price, $5.00 net. Reviewed by C. R. Young, C.E., Assistant Professor of Structural Engineering, University of Toronto.

Heretofore the engineer or student who found occasion to consult the literature of foundations was unable to turn to any comprehensive modern treatise on the subject. It is true that books in English on foundations have been available for some time, but none which could truly be said to cover the field fully, logically and in a manner suited to the needs both of the engineer and of the engineer-to-be. Professors Jacoby and Davis have admirably supplied this need in the present volume.

A cursory examination of the book is sufficient to impress the reader with the vast amount of labor involved in assembling and compressing within 600 odd pages the information presented to him. Perhaps there will be some who would wish that their own special methods or contrivances had received fuller consideration, but it is difficult to see how this could be done without disturbing the admirable balance preserved by the authors throughout.

A feature indicating the authoritative character of the book, if anything further than the standing of the authors themselves were needed, is the inclusion of a chapter on "Pneumatic Caisson Practice" by the well-known expert on deep foundations, T. Kennard Thomson, C.E., D.Sc., Consulting Engineer, of New York City.

Of the nineteen chapters, the first five are devoted to the subject of bearing and sheet piles. This is justified by the authors on the ground that young engineers are more likely to obtain their early experience with pile foundations than with any other class of foundation construction. Special

effort has been made to present the subject-matter relating to piles so as to meet the requirements of students without experience. Chapter I. is devoted to Timber Piles and Drivers, Chapter II. to Driving Timber Piles, and Chapter III. to Bearing Power of Piles. In describing the use of the water jet, no mention is made of a practice that has found favor in Canada, viz., loosening up the material into which the piles are to be driven by a water jet and then, after the jet is withdrawn, driving the pile before the material has had a chance to settle down firmly again. Concrete piles, treated in Chapter IV., receive special consideration in the matter of driving and bearing power, apart from the general discussion of these subjects in Chapters II. and III. Metal and Sheet piles are covered in Chapter V.

In Chapters VI. to XI., inclusive, the various constructions and methods adopted for placing foundations under water are given detailed treatment. The subjects considered are: Cofferdams, Box and Open Caissons, Pneumatic Caissons for Bridges, Pneumatic Caissons for Buildings and Pier Foundations in Open Wells.

Three chapters on piers and abutments are incorporated in the work for the reason that courses in masonry construction and foundations are frequently combined in engineering colleges.

An excellent chapter on spread foundations is included, numerical examples, both in steel grillages and reinforced concrete footings being worked out. In the footnote to Table 153 a, on page 461, the pressure on the earth in pounds per square foot is erroneously stated to be due to "dead, live, and dead plus live load." Reference to the table itself shows that this should be "dead, dead plus ½ live load and dead plus live load."

Two useful chapters are those on Underpinning Buildings and Explorations and Unit Loads. Logical, up-to-date treatments of these subjects in text-books have up to the present been lacking.

Chapter XVIII., by Dr. T. Kennard Thomson, concludes the text proper.

One of the most valuable features of the book is the extensive list of references to engineering literature contained in Chapter XIX. From this the student or engineer can carry his investigation of the subject to the limit of detail desired.

It is a pleasure to turn over the pages of a book exhibiting the evidences of authority and care in presentation characterizing the present volume. No engineer having to do with foundations can afford to be without a copy, and perhaps when the full merit of the work is realized none will care to undertake an unfamiliar piece of work without consulting it.

Modern Business.—Edited by Joseph French Johnson, Dean, New York University School of Commerce, Accounts and Finance. Published by the Alexander Hamilton Institute, New York. Canadian office, C.P.R. Building, Toronto.

This is a series of eighteen treatises, published in twelve volumes, forming the basis of a modern business course and service. While it does not touch upon engineering in all its departments, there are many sections from which the engineer may derive much instruction and benefit, as will be recognized from the following synopsis of the subjects included:—

Volume I., Applied Economics, by James Mavor, Professor of Political Economy, University of Toronto; Volume II., Organization and Management, by Lee Galloway, of New York University; Volume III., Selling, by Ralph Starr Butler, of University of Wisconsin; Credits, by Lee Galloway, of New York University, revised by W. W. Swanson, of Queen's University, Kingston; Traffic, by Hon. S. J. McLean, Member of Board of Railway Commissioners for Canada; Volume IV., Advertising, by Lee Galloway, of New York University; Correspondence, by George B. Hotchkiss, of New York University; Volume V., Accounting Practice, by Leo Greendlinger, of New York University, revised by E. W. Wright, of the Toronto Bar; Volume VI., Corporation Finance, by W. H. Lough, formerly of New York University, revised by Fred. W. Field, Managing Editor, *Monetary Times*, Toronto; Volume VII., Money and Banking, by Joseph French Johnson, of New York University, and Earl Dean Howard, of Northwestern University; Volume VIII., Banking Practice, by E. L. Stewart-Patterson, of the Canadian Bank of Commerce; Foreign Exchange, by Franklin Escher, Editor of "Investments," New York City, revised by E. L. Stewart-Patterson, of the Canadian Bank of Commerce; Volume IX., Investment and Speculation, by Thomas Conway, Jr., of University of Pennsylvania, revised by Fred. W. Field; Volume X., Insurance, by Edward R. Hardy, of the New York Fire Insurance Exchange, revised by Fred. W. Field; Real Estate, by Walter Linder, of the Title Guarantee and Trust Company, of New York City, revised by E. W. Wright, of the Toronto Bar; Volume XI., Auditing, by Seymour Walton, C.P.A., of Chicago, revised by E. W. Wright, of the Toronto Bar; Cost Accounts, by Stephen W. Gilman, of University of Wisconsin: Volume XII., Commercial Law, by W. S. Johnson, of the Montreal Bar.

The series as a whole is a complete and logical digest of the principles and practices of present-day business, and is a most valuable contribution to business literature. It has been entirely re-written for Canadian use, and should prove an important factor in improving business methods. Four of the treatises, those dealing with the conditions that are quite different in Canada from what they are in the United States, are entirely new. We refer to the treatises on applied economics, railway traffic, banking practice and commercial law. In the first, Professor Mavor, so well known among Canadian economists, has exhibited a wonderful knowledge of business conditions in Canada, and his work abounds in concrete information that is of great value to anyone interested in the economic problems of the country. It is as well a general introduction to the whole series, and touches upon almost all of the questions raised in the subsequent volumes. In the treatise on traffic Hon. J. S. McLean, of the Dominion Board of Railway Commissioners, has presented a complete and able discussion of the factors which govern freight rates in this country. The treatise is divided into 10 chapters devoted to the following phases of the subject: Canadian Transportation; Freight Classification; Freight Rates; Freight Rates in Practice; Phases of Rates and Tariff; Passenger Rates; Practical Phases of Railway Business; Express Service; Inland Water Transportation; Foreign Trade and Ocean Transportation. There has been so much partisan controversy in this field that it is a relief to find the subject treated with such marked impartiality. The work will undoubtedly be influential in bringing about a reasonable and mutually satisfactory agreement as to the traffic problems which exist.

Another volume that should prove of interest and value is devoted to "Organization and Management." This book, by Lee Galloway, the author of "Economics of Dock Management," has been pronounced the most comprehensive text on this subject that has so far appeared. At any rate, in the opinion of the reviewer, a knowledge of the principles which are set forth in this volume is a necessary part of the equipment of every present-day executive. It is on a subject, moreover, that is engaging the attention of progressive business men throughout the world.

There is a volume devoted to corporation finance which is an exposition of the principles and methods covering the promotion, organization and management of modern corporations. The information contained therein is largely

drawn from the experience of the big industrial and railroad companies, whose methods are well developed and worthy of study and imitation by the management of smaller corporations. The book on accounting practice is a comprehensive statement of accounting principles and methods illustrated by modern forms and problems. Chapters on capital and revenue, on depreciation and other reserves, render it a valuable book for the man in engineering and contracting from a business standpoint.

One often hears assertions respecting the value of the study of English in an engineering training. Engineers are frequently placed at a disadvantage, particularly young engineers, when called upon to make a report upon a certain problem, or a progress report as construction work goes on. Similarly, a lack of fluency in the expression of thought is to be found occasionally in an engineer's correspondence. Written expression of thought requires more care and consideration on the part of the writer than verbal expression, and those who have little writing to do are frequently at a loss to properly convey upon paper the intended meaning as they could readily do by word of mouth. One of the subjects which is given a careful study is in connection with correspondence. It takes up in a masterful way the art and its problems, the principles of construction and the essential points connected with letters of various kinds.

In the same volume is contained a treatise on advertising which the manufacturer and the salesman will find of exceeding value in his work.

In all, they should appeal strongly to mature business men who wish to supplement their practical experiences by getting into touch with the ideas and experiences of other successful business men, and to young men who are just getting well started in business, and who need, above everything else, to get a grasp on the principles which underlie modern business practice.

The whole series of texts is claimed by the publishers to be but a single feature of a complete modern business course and service which aims to make available for business men of Canada a fund of information that they cannot get out of their own experiences. The books have been well edited and bound in a durable flexible backing.

Steel Bridge Designing.—By Melville B. Wells, C.E., Associate Professor of Bridge and Structural Engineering, Armour Institute of Technology. Cloth; 6¼ x 9¼ ins.; 260 pages; 43 illustrations; 26 pages. Published by Myron C. Clark Publishing Company, Chicago. Price, $2.50 net.

This book is intended primarily for use in engineering colleges and also as a reference book in the drafting-rooms of bridge works. To the instructor, the student, and the man in the drawing office it can be well recommended.

The first three chapters treat the subject of bridge designing in a general way, Chap. 1 dealing with engineers' work and contracts; Chap. 2, bridge manufacture, and Chap. 3, rivets. The next six chapters relate to actual design, Chap. 4 containing the design of a 50-ft. roof truss, Chap. 5 discussing types and details of highway bridges, and so on, each chapter giving the detailed numerical computations of the example under consideration.

Chapter 11 has to do with shop drawings, their general considerations, arrangement, markings, dimensions, etc.

The subject of Strength of Materials is dealt with to the extent of 30 pages in Chap. 12. Sections of it are devoted to: centre of gravity, moment of inertia, radius of gyration, flexure and deflection of beams, shear, column formulas, latticing, combined stresses, pins and rollers, deflection of a truss, bending moment on plate girder webs, [illegible] gives briefly the derivations of the principal formulas used in bridge designing, with examples of their applications when such examples in other parts of the book are not referred to. With respect to its insertion, the author states: "The student is assumed to know the methods of calculating stresses, also to have studied the subject of strength of materials. In designing, however, it is often desirable to refer to a volume on mechanics or strength of materials. Such a volume is not always accessible, and the tendency is for students to fall into the dangerous practice of using formulas blindly, not knowing their derivations and correct applications."

Chap. 13 presents a bibliography of supplementary reading on the various subjects treated in the text, and should prove of great service to the reader. The closing chapter contains the general specifications for steel railway bridges adopted by the American Railway Engineering Association in 1910.

There are twenty-six folding plates of shop and general drawings, from which have been taken the examples used throughout the text. There are other good illustrations throughout the book, while its typography, press-work and binding are all very commendable.

PUBLICATIONS RECEIVED.

Annual Report of the International Harvester Corporation to December 31st, 1913.

Town of Oshawa, Auditor's Report for 1913.—Containing detailed statement, receipts and expenditures, assets and liabilities, and report of water commissioners.

Problems of the Petroleum Industry.—By Irving C. Allen, United States Department of Mines. Information derived from conferences at Pittsburg in 1913.

Wheaton District, Yukon Territory.—A 150-page bulletin listed as Memoir No. 31, Geological Survey Branch, Department of Mines, Canada. Prepared by D. D. Cairns.

Fires in Lake Superior Iron Mines.—By Edwin Higgins, of the United States Bureau of Mines. A 34-page illustrated pamphlet dealing with mine fires and their prevention.

Town Planning Act.—First draft of the Town Planning Act prepared by the Commission of Conservation, Canada, for discussion at the 6th annual conference on city planning.

International Conference of Mine-Experiment Stations.—Compiled by Geo. S. Rice as Bulletin No. 82, United States Bureau of Mines, concerning Pittsburg Conference, September, 1912.

Water Commissioners of London, Ont.—(35th Annual Report, 1913), of the city of London waterworks, electrical and parks department. H. J. Glaubitz, general manager. 124 pages; illustrated.

Mines Sign-Boards.—Technical paper No. 67, United States Bureau of Mines, dealing with the use of sign-boards in mines for various purposes and containing recommendations for universal symbols.

Efficient Use of Cars.—Booklet issued by the Westinghouse Electric and Manufacturing Company containing suggestions received from operating railway men on the efficient use of cars and cost of stops.

American Highway Association and American Automobile Association Proceedings of the 3rd American Road Congress, held in Detroit, September, 1913. 312 pages; [illegible] ins. Price, [illegible], postpaid.

Cedars Rapids Manufacturing and Power Company.—Third Progress Report (May, 1914), on the construction of the Cedars Rapids hydro-electric development on the St. Lawrence River. 28 pages; illustrated.

Climate of British Columbia. Tables of rain and snow fall and temperature; altitude of places, lakes and mountains. Second edition of Bulletin No. 27, Bureau of Provincial Information, British Columbia.

American Road Builders' Association.—Proceedings of the 10th annual convention, held at Philadelphia, December, 1913, including reports of executive committee, secretary-treasurer, etc. 320 pages; 6 x 9 ins. Price, $2.00.

Test of a Jet Pump.—By L. R. Balch, C.E., University of Wisconsin. Issued as Bulletin No. 596, engineering series. It presents a description of apparatus, methods of experiments and results and conclusions. Price, 25 cents.

Physical and Chemical Properties of the Petroleums of California.—Technical paper No. 74, United States Bureau of Mines, dealing with the collection, physical and chemical examination of samples and the results therefrom. 34 pages; 6 x 9 ins.

City Plan for Greater Berlin, Ont.—Prepared by Chas. W. Leavitt, New York City. 22 x 30 ins., locating streets, parks, railway lines, etc., through the commercial and residential districts. Also an industrial map of the city of Berlin, 13 x 15 ins.

International Waterways Commission, Canada.—Compiled reports (1905-13), It is a computation of all memoranda reports issued by the Canadian and American sections of the Commission during this period. 1224 pages; 6 x 9 ins.; containing numerous maps and drawings.

A Test of an 8-foot Flash Wheel.—Bulletin No. 598, University of Wisconsin. Prepared by L. R. Balch, C.E., research assistant in hydraulic engineering. It deals with experimental tests, methods, computations, discussion and conclusions. 58 pages; 6 x 9 ins.; illustrated.

Manitoba Public Utilities Commission.—Second Annual Report for the year ending November 30th, 1913. It includes applications, proceedings, orders, etc., together with Mr. R. M. Feustel's report, dated September 15th, 1913, on the Winnipeg street railway service. 152 pages; 6 x 9 ins.

St. Hilaire (Belœil) and Rougemont Mountains, P.Q.—By J. J. O'Neill. Published by Geological Survey, Department of Mines, Canada, as Memoir No. 43. It deals with the physiography, petrology, etc., of these mountains and of the strata in the neighborhood of each. 108 pages; 6 x 9 ins.

The Effect of the Soot in Smoke on Vegetation.—Bulletin No. 7, of the smoke investigation of the Mellon Institute of Industrial Research and School of Specific Industries, University of Pittsburg. An investigation begun in March, 1912, and continued through a year and a half by J. F. Clevenger, M.A. 26 pages; illustrated; 6 x 9 ins.

Infiltration and Leakage in Sewers.—A 61-page booklet published by the Union Clay Products Company, New Brunswick, N.J., containing discussion on the subject by leading authorities as found in proceedings of various societies and other publications. It contains specifications and directions for using joint compound manufactured by the publishers.

American Wood Preservers' Association.—Proceedings of 10th annual meeting, held at New Orleans, La., Jan. 20, 21 and 22, 1914. 408 pages; 6 x 9 ins.; illustrated. The volume contains an account of the convention, papers presented, constitution of the Association, list of members, and statistical information respecting the use of preservatives during 1913.

Investigation of Flow through Large, Submerged Tubes.—Bulletin No. 629, Engineering Series, University of Wisconsin, Part 3, of experiments with submerged draft tubes. By Geo. J. Davis, Jr., C.E., and L. R. Balch, C.E. A description is given of the apparatus used, methods of experimentation and computation and general discussion of results. 57 pages; illustrated.

Geological Notes and Map of Sheep River Gas and Oil Field, Alberta.—Memoir No. 52, Geological Survey, Department of Mines, Canada. Prepared by D. B. Dowling. It contains a description of the geological formations, occurrences of gas and oil in the general region, oil-bearing horizons in various States, and notes on the origin of oil and gas. 26 pages; illustrated.

The Cement Gun and Its Work.—Reprint of a paper read before the Western Society of Engineers, Chicago, by Carl Weber, descriptive of the cement gun, a machine for "shooting" a coating of cement mortar upon construction surfaces, such as concrete, brick, tile, wood and steel work, by the aid of compressed air. Distributed by the Gun-Crete Company, McCormick Building, Chicago.

Investigation of Hydraulic Curve Resistance Experiments with 3-inch Pipe.—Bulletin of the University of Wisconsin, No. 578. Prepared by L. R. Balch, C.E., research assistant in hydraulic engineering under direction of Prof. Geo. J. Davis, Jr., and Prof. Daniel W. Mead. It describes the apparatus used, methods of experiment, computation of results and theoretical consideration of loss of head in bends. 52 pages; 6 x 9 ins. Price, 25 cents.

Safety and Efficiency in Mine Tunnelling.—By D. W. Brunton and J. A. Davis, United States Bureau of Mines Bulletin No. 57. 270 pages; illustrated; 6 x 9 ins. The bulletin deals with various phases of tunnelling operations, describes surface and underground equipment, tunnel construction methods, cost and history of tunnelling. A section is devoted to the cause and prevention of tunnel accidents.

Siphon Spillway Automatic Crest for Dams.—A 16-page booklet issued by the Hydraulic Specialties Company, Limited, Albany, N.Y., describing the two devices invented by Mr. G. F. Stickney for regulating the water level in a canal stream or reservoir and for providing for the disposal of surplus water in time of flood. These devices have been adopted on the New York State Barge Canal, in connection with which Mr. Stickney was a designing engineer.

Abstracts of Current Decisions on Mines and Mining.—By J. W. Thompson, United States Bureau of Mines. It treats of the following subjects: minerals and mineral lands; mining corporations; mining claims; mines and mining operations and statutes relating thereto; mining leases; mining properties; damages for injuries to miners; and operation of quarries. The information contained therein covers investigations made from March to December, 1913. 140 pages; 6 x 9 ins.

Sewer Flushing and Its Cost.—Published by Merritt Hydraulics Company, Philadelphia. 102 pages; 146 illustrations; 6 x 9 ins. This is the second edition of an interesting and useful book on sewer flushing, including a discussion of the cost of flushing at various intervals, ranging from every day to once or twice a week. It includes also a discussion on the design of flush tanks to secure reliability, to prevent water waste, and to secure any frequency of discharge. It has an appendix on sewage pumping and sewage disposal apparatus, and sewer jointing. The book contains the results of experiments and the statements of authorities regarding such important items as the conditions under which deposits will form in a sewer system and flushing will be needed, the amount of flushing water required, and the effectiveness of a flush wave. The reader is referred liberally to available literature in various books and reports and to the files of the leading engineering periodicals.

Engineer's Hand-Book.—A 581-page illustrated handbook of tables, charts and data on the application of centrifugal fans and fan system apparatus, including engines and motors, air-washers, hot blast heaters and systems of air distribution. Published by the Buffalo Forge Co., Buffalo, N.Y., and edited by W. H. Carrier, chief engineer. First edition, 1914. $[illegible]

This book has very complete information for the engineer and the architect on the fundamental principles governing the selection and application of fans for various purposes. It is intended to be used as a guide for them with respect to the above appliances. It indicates that an effort has been made to so standardize the rules and data given that they may be used with any standard make of equipment. The book contains results of tests and research by the engineering staff of the company, much of which has been heretofore published in the proceedings of some of the engineering societies. The information which the book contains is complete and reliable.

CATALOGUES RECEIVED.

Air Compressors.—Four-page illustrated folder, issued by the Canadian Ingersoll-Rand Company, Limited, Montreal, descriptive of several types of convertible steam or belt-driven compressors.

Hydraulically and Electrically-Operated Valves.—Booklet No. 6 of the Rensselaer Valve Company, Troy, N.Y., illustrating various types and sizes, and also clutch attachments for power-operated valves.

Porcelain and Glass Insulators.—A 16-page illustrated bulletin of the Westinghouse Electric and Manufacturing Company descriptive of high-voltage porcelain pin-type and wall insulators and bushings.

Electric Hoists.—A handsomely compiled, 32-page illustrated catalogue describing Sprague electric hoists in capacities from ½ to 6 tons. Canadian General Electric Company, Limited, Toronto, selling agents.

Air-Compressors and Vacuum Pumps.—Eight-page illustrated pamphlet of the Merta Machine Company, Pittsburg, describing their automatic plate valve (Iversen patent) and its advantages; and also their vacuum pumps.

Push-Button Control for Industrial Plants.—An illustrated catalogue descriptive of push-button control as a safety device of importance for manufacturing plants, issued by the Canadian General Electric Company, Toronto.

Aztec Liquid Asphalt for oiling roads. A 28-page illustrated booklet issued by the United States Asphalt Refining Company, containing useful information pertinent to Aztec Asphalt, its source, preparation, qualities, methods of using, and reports of analyses and tests.

Valves and Hydrants.—Catalogue No. 5 and price list of the Kerr Engine Company, Walkerville, Ont., descriptive of brass angle check, globe, gate, radiator and swing check valves; also fire hydrants, flanges, floor stands, indicator posts water cranes, etc. 60 pages; fully illustrated.

Pile Hammers.—A 28-page illustrated booklet of the McKiernan-Terry Drill Company (Canadian agents, Canadian Allis-Chalmers, Limited, Toronto). It depicts the characteristic features of this type of light and heavy-duty hammers, and illustrates a wide variety of uses. Dimensions, prices, specifications, etc., are included.

Good Pavements and Roads in the South.—A handsomely illustrated 24-page booklet descriptive of highways in the Southern States that have been built with Trinidad and Bermudez Lake asphalts, and explanatory of essential features in the construction and maintenance of such roads. Issued by the Barber Asphalt Paving Company, Philadelphia, Pa.

Pneumatic Concrete Mixers.—A handsomely illustrated catalogue issued by the Pneumatic Concrete Placing Company of Canada, Montreal and descriptive of mixers and conveyors and of the operation of mixing and placing concrete by means of compressed air. Some interesting construction views are given of this machinery in use. The above company are Canadian agents for J. H. MacMichael, Chicago.

Centrifugal Pumps.—A 298-page illustrated catalogue of the DeLaval High Efficiency Centrifugal Pumps of single and multi-stage types for various capacities and heads. It is known as catalogue "B," and deals with their characteristics, design, manufacture, testing, selection and adaptation to various uses. It contains special chapters on speed-reducing gears and turbine-driven waterworks pumps. An interesting illustration is that of a 100,000,000-gal. centrifugal pump under test prior to installation in Pittsburg. Another cut illustrates a 16,000,000-gal. steam turbine-driven centrifugal pump, now being installed in Toronto, when under test.

The Industrial Harbor.—A 152-page illustrated booklet descriptive of cranes and transporting appliances of various kinds for the quick handling of goods in modern commercial harbors. Issued by the Demag-Duisburg Deutsche Maschinenfabrik A.G., Germany. Illustrations are given of various harbors throughout the world where there are in operation cranes of the electric travelling, revolving, electrically-driven locomotive, electrical slewing, tower-revolving, grab and portable steam, locomotive jib, electric stationary, semi and full portal, portable and slewing gantry, electrical dischargers, and various other types of cranes, etc. Coal and ore-unloading and transporting plants of various types are included.

PROPOSED AUTO-HIGHWAY IN ENGLAND.

A bill is to be brought before the British Parliament to secure approval for the construction of a highway exclusively confined to automobile traffic, which will be about 50 miles long and 150 feet wide. It is estimated that it will cost $25,000,000; and it is to be constructed by the London, Brighton, and South Coast Motor Road Syndicate Company, Limited. The roadbed proposed is of reinforced concrete with a bituminous surface. Brighton is selected as the southern terminal and Richmond as the entrance of the highway, which will be provided with 3 tracks—the first for fast traffic, the second for heavier vehicles, and the third for autocycles and cyclecars. Wherever the present main roads cross the new roads, bridges will be built; and interference with any other traffic will thus be avoided. According to the plans the entrance to the road at Richmond will be in the form of an ornamental stone arch and a rectangular building for garages, workshops and the sale of accessories. At various points on the road there will be grandstands and workshops. The stands will be for the observation of auto racing on certain specified days, and the workshops for hauling broken-down cars from the road and repairing them. At Brighton terminus there will be ornamental gardens and a bandstand.

The Wabamun Power and Coal Company, of Edmonton, Alta., is preparing to establish a thoroughly modern power plant on its property situated at Wabamun, and has delegated C. J. Grierson and J. Wilson, expert engineers, to visit all the power plants situated in the large cities of the Pacific Coast and middle west states in order to collect first hand information as to the best type of machinery to secure for installation, as well as the cost of the same. R. D. Fetherstonhaugh, mining expert, at present employed with the company, states that three copper and silver claims have been obtained by him for the company in the Omineca country, ore from which is yielding $100 worth of silver per ton. Mr. Fetherstonhaugh will also stake anthracite coal and other claims for the company in the Dunvegan district.

Coast to Coast

Wexford, Ont.—The bridge over the C.P.R. tracks near Wexford, known as the town line bridge, has been completed and opened for traffic.

Medicine Hat, Alta.—It is reported that the Medicine Hat Brick Co. has now in full operation its large plant at Medicine Hat. From 50,000 to 75,000 bricks are being manufactured daily.

Moncton, N.B.—City Engineer Edington, of Moncton, N.B., has submitted for the consideration of the civic board of works plans for street paving for 1914 involving an expenditure of $44,000.

Montreal, Que.—On the recommendation of the board of control, the Montreal city council has voted $294,634.31 to be used mostly in the construction of buildings in connection with various civic departments.

Sussex, N.B.—The new I.C.R. station at Sussex is practically complete and ready for occupation. Also the siding at the military grounds is being improved, and the loading platform is being extended considerably.

Victoria, B.C.—Actual work on the excavation of the 10 miles of trench necessary for the steel pressure pipe line for the Sooke Lake waterworks system between Humpback Reservoir and the city, has been commenced.

Hamilton, Ont.—Estimates have been prepared to be brought before the Wentworth County council amounting in all to approximately $100,000, of which the chief estimate is a road work appropriation amounting to $46,837.60.

Ottawa, Ont.—The Public Works Department or the Ottawa Government has commenced operations on undertakings consisting of harbor and river improvements, and of public buildings, which will aggregate an expenditure of $46,000,000.

Rosser, Man.—A satisfactory adjustment of disputed points has been arranged between the municipal council of Rosser, Man., and governmental authorities in charge of the good roads department; and active road construction in the Rosser district has recommenced.

Halifax, N.S.—It is reported from Halifax that contractors are organizing to commence the construction of a mile of seawall, forty feet high from the bottom and on two great piers, the whole of which construction work will cost $5,000,000.

Canora, Sask.—It has been announced that the present season will see the completion and operation of the new C.N.R. branch from Canora northward as far as Sturgis, a distance of 22 miles. Also two stations are expected to be constructed between these points.

Moose Jaw, Sask.—Engineer Commissioner Mackie has presented to the Moose Jaw city council a report on street grading done during the month of May, showing that 18,000 cubic yards of excavations have been completed at a cost of $46,000, which means an average of about 25 cents per cubic yard.

Halifax, N.S.—A news item from Halifax states that the civic authorities are at present taxed to the utmost to keep the works in progress up to date; that street, sewer, and sidewalk construction is proceeding rapidly, the Clerk of Works having paid out about $12,000 for the past fortnight's labor.

Vancouver, B.C.—The C.N.R. company has placed an order for 45,000 tons of steel rails for the completion of its lines in British Columbia. Five thousand have already been shipped from Sydney, C.B., to Port Mann, B.C.; 5,000 are to be shipped to the Vancouver Island line; 8,000 will be delivered to Kamloops; and 17,000, to the present end of steel, south of Yellowhead Pass.

Calgary, Alta.—Crude black petroleum has been struck at the well of the Monarch Oil Company on section 5, township 32, range 6, west of the fifth meridian, at a depth of 808 feet. The well is about 30 miles west and 6 miles south of the town of Olds, on the Calgary-Edmonton line of the C.P.R., while the Dingman well is about 65 miles southwest of Calgary. At the Dingman well, light oil was struck at a depth of 2,700 feet.

Vancouver, B.C.—An announcement has been made at Ottawa to the effect that the Dominion Government has selected as a site for the new $1,000,000 transfer elevator to be built at Vancouver, a point on the Government dock in Vancouver harbor; and that tenders will be called for the structure within a couple of months. Plans are to be prepared at once. It is expected that the cost will be between $750,000 and $1,000,000.

Winnipeg, Man.—The works and property committee of the Winnipeg city council has estimated that, during the season of 1914-1915 in Winnipeg, public works will cost about $106,900. Of this amount, $15,200 will be required for the maintenance and repair of bridges, $15,000 for street grading, $47,000 for sewer maintenance, $4,000 for sewer ventilation test, etc. The estimated expenditure during 1913 was $101,483; but the actual cost proved to be $116,665.44.

Medicine Hat, Alta.—It is reported from Medicine Hat that building operations totalling an expenditure of $1,500,000 are showing signs of preparation for construction in that city. Some of the structures are a brick and stone block being built by Thomas Mulligan, the enlargement of the present post-office building, the "News" building, a new technical high school, the enlarging of the mill property of the Lake of the Woods Milling Company, and the plant for the Maple Leaf Milling Company.

Victoria, B.C.—It is announced that the first contract to be completed in connection with the Sooke Lake waterworks scheme has just been executed by Messrs. Watson & Cousins, to whom the work of the construction of the telephone line from the lake to Humpback Reservoir, a distance of 27 miles, was let at a figure of $426 per mile. The telephone line is a double metallic circuit, and connects up numerous stations along the line of the pipe grade. Connection with the Humpback Reservoir end of the line will be made into the city.

Galt, Ont.—The Dominion Natural Gas Co. has experienced some difficulty in connection with the construction of the proposed purification plant for Tilbury gas. Delay was caused in the commencement of operations due to the fact that for a certain portion of the work only two firms on the continent were able to tender. It has now been finally decided to build the plant is 3 units, the first of which it is expected to have in operation in a month or six weeks. The other units will be completed within a month and two months, respectively, subsequent to the completion of the first unit.

Windsor, Ont.—It is said by Sir Adam Beck that the work on the Windsor-St. Thomas extension of the Ontario Hydro-Electric Commission's power line, has progressed sufficiently to warrant power being available by the end of July. The engineers are now preparing to make the connection with the local distributing stations at Windsor and Walkerville. For the low-tension line connecting Dresden, Tilbury, Wallaceburg, Strathroy, Lambeth, Embro, Plattsville, Priceville, Fergus, Elora and other places, orders have been placed for the material, some of which has been delivered.

Winnipeg, Man.—The following report on the output from the Winnipeg civic quarries for the month of May, 1914, and the corresponding month of last year, has been published. In 1914, from Stony Mountain, the output of

crushed stone was 183 cars, containing 5,570 yards; [illegible] and [illegible] yards. In 1914, from Bird's Hill, the output of gravel was 189 cars containing 5,370 yards; in 1913, 213 cars and 6,440 yards. In 1914, the sales to the city storekeeper were 4,575½ yards crushed stone, 3,419 yards gravel, 91 yards sand, and 34 yards granite, a total of 8,119½ yards. Last year the sales were: crushed stone, 9,416 yards; gravel, 6,427 yards; sand, 388 yards; granite, 39 yards.

Toronto, Ont.—The contracts which have just been let by the Hydro-Electric Power Commission of Ontario in connection with the development of power at Eugenia Falls, will involve an expenditure of $230,000. The work entailed is the construction of dams, canals and penstocks. Dam No. 1 will be a reinforced concrete structure 2,000 feet long, and varying in height from 40 to 50 feet; while Dam No. 2 will be similar, though not as large. Tenders are now being called for the necessary hydraulic and electrical equipment, which will be used to develop 4,000 horsepower; although the headworks, canals and storage reservoir of the undertaking contemplate an ultimate development of 8,000 horsepower.

Victoria, B.C.—The estimated cost of the work to be undertaken at Songhees Point, Victoria, B.C., and for which tenders are being called, is about $250,000. A retaining wall, approximately 2,000 feet long and 6 feet above high water mark, extending from Songhees Point to the proposed Johnson Street bridge, is to be constructed; and 13 acres of land must be reclaimed. The successful contractors will probably have the option of two alternative schemes in connection with the construction of the retaining wall. One will be by surrounding the site by a cofferdam for the construction of the concrete in the dry, while the other alternative may be by means of cribwork. Considerable dredging will have to be carried out, as it is proposed to have 20 feet of water outside the retaining wall at low tide.

Cobalt, Ont.—A report from Cobalt states that about 120 feet of the Dominion Government 400-foot dam at the foot of Lake Timiskaming, has fallen away; and the cause for this is as yet unfathomed. The portion of the dam affected includes 3 piers on the Quebec side of the dam in the deepest part of the channel, 60 feet of sluice gates and 60 feet of piers. This dam was erected at the foot of the lake at South Timiskaming, and has given considerable trouble previously to the engineers. The water in the lake is falling very fast; and it is estimated that ultimately it will fall ten feet in consequence of this break. This will mean that the new wharf at Ville Marie will not be approachable by boats. The new wharf at Paradis Bay will be in a similar position. The wharves at New Liskeard and Haileybury will be effected only in a minor degree, since there is much better harborage at these points.

Vancouver, B.C.—The mining committee of the Vancouver Board of Trade recently reported to the board in reference to the advisability of encouraging the establishment of an iron and steel industry in Vancouver. The committee stated that there are ample supplies of raw material in the form of magnetite ore on Texada, Nelson, Redonsda and other islands, and on the east and west coast of Vancouver Island. There are supplies of limonite ore at Quatsino, Barclay Sound, Green Lake, Chilliwack and other accessible points. Hematite ores are reported from Bella Coola, Bute Inlet and other points. Vancouver Island coal can be converted into suitable coke by the use of proper retort ovens; while there is plenty of limestone for fluxing to be had at nearby points. The committee also stated that pig iron could be produced at $12.53 a ton, and added that there [illegible] market for [illegible] tons a year at $25 a ton. If local coal cannot be made into proper coke the government is willing to remit the tax on coal imported for coking. There are no known deposits of iron ore of commercial value on the Pacific coast south of British Columbia, but the copper ore shipped out of British Columbia in 1913 totalled 352,300 tons, valued at $3,035,540.

Vancouver, B.C.—Announcement is made to the effect that, between the Okanagan section of the Kettle Valley Railway, rail connections are now in course of construction along the entire route from Midway to Hope, which are to be completed within the next 3 months. The completion of a 15-mile link between Carmi and Penticton will mean that the entire line from Midway to Osprey Lake will be ready for service. Along this section, it is stated that bridge building is proceeding rapidly south of Penticton; and steel has been laid to Osprey Lake from which point a section of line is being built to Penticton. All recent publications in connection with progress being made with all sections of the Kettle Valley road, as well as the section of the V.V. and E., which is to be used conjointly by the two roads, would indicate that rail connection between the boundary and Okanagan points and Merritt, will be completely established this autumn.

Fraser River, B.C.—The work which is provided for by the sum of $60,000 included in the supplementary estimates of the Dominion Government, is the removal of obstructions from the Fraser River, so as to construct a permanent passage for fish to their spawning grounds. Work has been in progress for some time at Hell Gate in the Fraser Canyon, where the river is only about 100 feet wide, and where last December the channel was made considerably narrower by a slide caused by the falling in of the C.N.R. tunnel just above Hell Gate. The contract for the dredging of the channel was given to the Pacific Dredging Company about three months ago; but another six months will be required to complete the work. Night and day shifts have been at work during the past months, and have been moving from 1,000 to 1,500 yards of heavy rock from the bottom of the river to a ledge on the C.P.R. side, 175 feet above water. The rock is being lifted and carried by an overhead cable way which carries a weight of up to 15 tons at each trip and moves 30 feet per second. It is stated that the type of carriage in use is the only one in Canada. It was made in Pittsburg, and carries either buckets full of small rock, or hooks on to 10 or 12-ton rocks. Mr. Stuart Cameron, vice-president of the company, has said that no less than 46 tons of dynamite are being used in the work.

Victoria, B.C.—Mr. J. S. MacLachlan, Government supervising engineer on the breakwater and pier contracts at Victoria, has announced that, during the month of May, 54,114 tons of rock were dumped at the Ogden Point breakwater site. This is a material advance on the amount accomplished in April; while it brings the total amount of rubble dumped since the breakwater contract was started up to 126,504 tons. The increase in May is attributed to the use of a dredge with a capacity of 500 tons. Also, during the month of May, 1,190 tons of granite blocks were laid on the rubble bed under the supervision of divers. Altogether, 1,000 cubic yards of material were excavated and levelled off on the foreshore area during May. This amount is considerably smaller than in previous months. At the site of the piers, during the past month, 7,036 tons of rip-rap were dumped; which material is to form the foundation of the concrete cribwork that is to be constructed on the big floating drydock now moored inside the Inner Harbor. The first shipment of steel is on its way overland to Victoria from the plant of Prior & Co., Nova Scotia; and cement is now under order from the Associated Cement Company, of Bamberton. The Grant Smith & McDonnell quarries at Esquimalt, whence much of the rubble for the contract will be secured, are being opened up; and it is expected that material will be shipped from that point this month.

PERSONAL.

JAS. L. TAYLOR, formerly road superintendent for the County of Wentworth, Ont., has gone to Parry Sound, to accept a similar position there.

A. G. HAULTAIN, for the Canadian Geological Survey, is making a survey of Lake Athabasca, which will serve as a base for all explorations and surveys in the surrounding region.

HANS DEMPWOLFF and TURT SEMMIER, two engineers of the Prussian State Railway System, have been spending several weeks in Canada on an inspection trip of Dominion lines.

THOS. R. LOUDON has been appointed assistant professor of ferro-metallurgy; A. T. LAING, assistant professor of applied mechanics; and A. W. McCONNELL, assistant professor of architecture, at the University of Toronto.

R. L. DOBBIN, B.A.Sc., has been appointed Waterworks Superintendent for the City of Peterborough, Ont. Mr. Dobson has been connected with water supply works in various capacities throughout Canada. A few years ago he was associated with the construction of the Moose Jaw supply line from Caron, Sask.

C. D. KAEDING, formerly assistant general manager of the Goldfield Consolidated, and recently assistant superintendent of mines for the Canadian Copper Co., has been appointed vice-president and general manager of the Dome Mines, Limited, South Porcupine, Ont., and has taken charge of the property, Mr. H. C. Meek, his predecessor, having recently resigned.

OBITUARY.

The Grand Trunk Railway System has suffered a loss through the recent death of Mr. M. M. Reynolds, its vice-president, who for many years had charge of the financial and accounting departments.

A prominent engineer in the person of Mr. Alex. Stewart, assistant chief engineer, Great Northern Railway, died in Seattle, a few days ago. Mr. Stewart was well known in Victoria and Vancouver. The reclamation work at False Creek, the dock on Burrard Inlet, and the other development work carried out by the G.N.R. in Vancouver was done under his supervision.

The death occurred recently in Victoria, B.C., of T. H. Parr, at the age of 66. He was born in England and came to Canada at an early age entering the engineering department of the City of Winnipeg. In 1890 he went to Victoria and engaged in private practice as civil engineer and surveyor. In 1892 he was appointed assistant city engineer of that city under Mr. E. A. Wilmot, and held office for many years. Of late he has not taken an active part in professional affairs.

Owing to the resignation of its secretary, Mr. W. H. Rosevear, the Western Canada Railway Club has, as acting secretary until the annual elections in September, Mr. Louis Kon, Immigration Agent, G.T.P. Ry., Winnipeg.

The 7th annual meeting of the Mine Inspectors' Institute of the United States was held in Pittsburg, a few weeks ago. A large number of delegates from Canada and also from Mexico, were in attendance.

REGINA ENGINEERING SOCIETY.

The personnel of the Regina Engineering Society executive for the present year is as follows:—President, H. S. Carpenter, Board of Highway Commissioners, Saskatchewan Government, Regina; first vice-president, L. A. Thornton, City Commissioner, Regina; second vice-president, R. O. Wynne-Roberts, Consulting Engineer, City Hall, Regina; secretary, J. M. Mackay, Superintendent of Waterworks, Regina; treasurer, R. N. Blackburn, Chief Boiler Inspector, Saskatchewan Government, Regina.

COMING MEETINGS.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30th to July 4th, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—Summer convention to be held at Brighton Beach, N.Y., July 3rd and 4th, 1914. Secretary, J. R. Wemlinger, 11 Broadway, New York.

UNION OF CANADIAN MUNICIPALITIES.—Annual Convention to be held in Sherbrooke, Que., August 3rd, 4th and 5th, 1914. Hon. Secretary, W. D. Lighthall, Westmount, Que. Assistant-Secretary, G. S. Wilson, 402 Coristine Building, Montreal.

WESTERN CANADA IRRIGATION ASSOCIATION.—Eighth Annual Meeting to be held at Penticton, B.C., on August 17, 18 and 19. Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

AMERICAN PEAT SOCIETY.—Eight Annual Meeting will be held in Duluth, Minn., on August 20th, 21st and 22nd, 1914. Secretary-Treasurer, Julius Bordollo, 17 Battery Place, New York, N.Y.

CANADIAN FORESTRY ASSOCIATION.—Annual Convention to be held in Halifax, N.S., September 1st to 4th, 1914. Secretary, James Lawler, Journal Building, Ottawa.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Seventh Annual Meeting to be held at Quebec, September 21st and 22nd, 1914. Hon. Secretary, Alcide Chausse, 5 Beaver Hall Square, Montreal.

CONVENTION OF THE AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—To be held in Boston, Mass., on October 6th, 7th, 8th and 9th, 1914. C. C. Brown, Indianapolis, Ind., Secretary.

AMERICAN HIGHWAYS ASSOCIATION.—Fourth American Road Congress to be held in Atlanta, Ga., November 9th to 13th, 1914. I. S. Pennybacker, Executive Secretary, and Chas. P. Light, Business Manager, Colorado Building, Washington, D.C.

AMERICAN ROAD BUILDERS' ASSOCIATION.—11th Annual Convention; 5th American Good Roads Congress, and 6th Annual Exhibition of Machinery and Materials. International Amphitheatre, Chicago, Ill., December 14th to 18th, 1914. Secretary, E. L. Powers, 150 Nassau St., New York, N.Y.

The City of London, Ont., has 13,978 water services supplied by its Waterworks Department.

A large deposit of silica sand has just been discovered near Redcliff, Alta. Under test it withstands a temperature of 3,000° and possesses properties which indicate its suitability in clay products, iron works and rolling mills. The discovery has aroused considerable interest in Redcliff.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21978—June 15—Directing that, within 60 days from date of this Order, C.P.R. install improved type automatic bell at crossing of main approach to Hospital for Insane, London, Ont.; 20 per cent. cost of installing bell be paid out of "Ry. Grade-Crossing Fund," remainder by Railway Company.

21979—June 13—Directing that, within 60 days from date of this Order, Pere Marquette R.R.Co., install improved type of automatic bell at crossing of Head St. (Longwoods Road), Chatham, Ont.; 20 per cent. cost installation be paid out of "Ry. Grade-Crossing Fund," remainder by P.M.R.R. All train movements on siding be flagged over by one of Company's yardmen.

21980—June 8—Approving agreement entered into between Bell Telephone Co. of Canada and King Telephone Co., Limited, dated May 28th, 1914.

21981—June 13—Establishing collection and delivery limits of Dominion Express Co., in town of Morse, Saskatchewan.

21982—June 12—Authorizing C.P.R. to open for traffic its line from Bassano to Empress, mileage 0.0 to 118.3; and from Empress, mileage 111.8, to mileage 110.8, Swift Current Northwest Branch, subject to and upon condition that trains operated over portion from mileage 0 to 75 be limited to speed not exceeding 20 miles an hour; from mileage 75 to 118.3, 18 miles an hour; and from mileage 110.8 to 111.8, 18 miles an hour.

21983—June 12—Approving location G.T.P. Branch Lines Co., station at Lorlie, Sask., Sec. 26-21-10, W. 2 M., Melville-Regina Branch; Station to be in accordance with Co.'s standard Structural Plan No. 1.

21984—June 13—Authorizing G.T.R. to construct siding into premises of Sarnia Bridge Co., Limited, from Sarnia Tunnel Station Yard.

21985—June 11—Authorizing Dominion Atlantic Ry. to construct siding to warehouse of W. H. Chase and Co., Avonport, Co. Kings, N.S.

21986—June 15—Authorizing Lake Erie and Northern Ry. to connect its tracks, temporarily, with siding of M.C.R.R. at Waterford, Ontario.

21987—June 15—Authorizing Esquimalt and Nanaimo Ry. to construct siding for Spragge and Company at mileage 1.35 west of Victoria, B.C.

21988—June 13—Authorizing C.N.O.R. to construct, temporarily, across public road between Lot 19, R. 1, and Lots 23 and 24, North Front A, by spur to Ballast Pit, Tp. Westmeath, subject to conditions contained in resolution.

21989—June 13—Authorizing C.P.R. to use Three (3) bridges—No. 30.8, near Kendry Station, Ont., No. 33.5, near Cavan Station, Ont., and No. 39.4, near Bethany Jct. Station, Ont.

21990—June 15—Amending Order No. 21915, dated June 1st, 1914, by striking out words "Campbellford, Lake Ontario and Western," in recital to Order, and substituting therefor words "Ontario and Quebec."

21991—June 15—Authorizing C.P.R. to re-construct Bridge No. 34.6 on Toronto Subdivision, Ont. Div., at Cavan, Ontario.

21992—June 8—Authorizing G.T.P. Ry. to construct Five (5) Bridges—across creek, mileage 151 east of Prince Rupert; across Shames River, mileage 79, Prince Rupert East; across Hardscrabble Creek, mileage 113.3, Prince Rupert East; across Creek at mileage 115.8 east of Prince Rupert; and across Sand Creek, mileage 115.1, Prince Rupert East, B.C.

[illegible]—June [illegible]—Authorizing C.N.O.R. to open for traffic Orillia Branch from junction with its main line at Udney to Atherley, Ont.; and rescinding Order No. 11308, dated July [illegible]

21994—June 16—Authorizing G.T.P. Ry. to construct spur in S.E. ¼ of Sec. 36-52-2, W. 5 M., mileage 823.64, Dist. North Alberta, Alta., for Alsip Brick and Supply Co., Limited.

21995—June 16—Authorizing G.T.R. to reconstruct bridge No. 301 across Indian River, mile post 105.80, near Thornbury, 14th Dist, of its line, Tp. Collingwood, Ontario.

21996—June 16—Amending Order No. 21114, dated December 30th, 1913,— 1. by inserting word "unopened" before word "highway," where same occurs in recital and operative part of Order. 2. By striking out words and figures, "the said crossings to be constructed in accordance with the Standard Regulations of the Board Affecting Highway Crossings, as amended May 4th, 1910."

21997—June 16—Amending Order No. 21496, dated March 17th, 1914, by inserting word "unopened" before word "highway" where it occurs in Order, and striking out words, "the said crossing to be constructed in accordance with Standard Regulations Affecting Highway Crossings, as amended May 4, 1910."

21998—June 16—Amending Order No. 21495, dated March 17th, 1914, by inserting word "unopened" before word "highway," where it occurs in Order; and striking out words, "the said crossing to be constructed in accordance with Standard Regulations of Board Affecting Highway Crossings, as amended May 4th, 1910."

21999—June 10—Authorizing C.P.R. to construct diversions in Secs. 19 and 29-7-27, W. 2 M., Sask., and construct Weyburn-Stirling Branch Line, at grade, across North and South Road Allowance between Secs. 19 and 30, and Secs. 20 and 29-7-27, W. 2 M., mileage 94.36; and rescinding Order No. 19746, dated July 4th, 1913.

22000—June 15—Directing that C.P.R. provide and construct highway crossing over its railway, Lot 5, Con. 2, Tp. Rayside, Ont.

22001—June 16—Authorizing Winnipeg River Ry. Co., to connect with C.P.R. at Lac Du Bonnet, Manitoba.

22002—June 19—Amending Order No. 21890, May 27th, 1914, by inserting after word and figures, "Sec. 3," in part 1 of recital to Order, word and figure, "Twp. 8;" and striking out figure "8," after word "Twp.," in said part 1, and 2nd paragraph of operative part of Order, and substituting figure "7."

22003—June 19—Amending Order No. 21891, May 27th, 1914, by striking out figures "512" in 2nd line of recital, and substituting therefor figures "312."

22004—June 16—Approving location C.N.R. through Twps. 18-20, R. 7, East of Principal Meridian, Man., mileage 48.56 to 62.72.

22005—June 10—Authorizing C.N.R. to construct across and divert road in S.E. ¼ Sec. 7-43-19, W. 4 M., Alberta.

22006—June 16—Authorizing C.N.R. to re-construct bridge across Red River, at Emerson, Man., subject to condition that Co., at own expense, construct guide pier or protection work should be called upon to do so at any future time by Dept. Public Works of Canada, in interests of navigation.

22007—June 8—Approving agreement entered into between Bell Telephone Co. and Municipal Corporation of Tp. Brooke, dated May 13th, 1914.

22008—June 16—Authorizing C.P.R. to construct stringer opening at Bridge No. 111.45, Hamilton and Goderich Sub. Div., at crossing of Wellington St., town of Goderich, Ontario.

22009—June 16—Authorizing G.T.R. to reconstruct Bridge No. 35, mile post 111.46, 30th Dist., Ottawa, Div., over South Indian River, near South Indian, Tp. Cambridge, Ontario.

22010—June 15—Directing that on and after date of this Order, Sarnia St. Ry. Co., bear and pay cost of maintaining and repairing diamond required to be installed at crossing of G.T.R. by Sarnia St. Ry.; rescinding Order No. 21825, May 14th, 1914, and this Order be without prejudice to rights of G.T.R. or Sarnia St. Ry. with reference to maintenance and repair under Order No. 138.
